1. INTRODUCTION

Civil works require considerable amount of natural resources and produce large amounts of waste. For many years, the construction industry has been following a model of extraction, production, use and discard. In the last decades, the awareness about sustainability bringing us to consider development model based on a circular economy. The concept of a sustainable economy is centred on the reduction of the generation of waste, and on the reuse of materials by means of recycling. Considering the construction industry, national and international authorities started to move to a cradle-to-cradle approach, which accounts for the whole life cycle of the materials from the production to their recovery and recycling process. The European Union has introduced the waste framework directive (European Parliament, Waste Framework Directive 2008/98/EC, 2008) which requires the member states to achieve a minimum of 70% construction and demolition waste (CDW) reuse. The ISPRA report (ISPRA, 2021) states that in 2019, in Italy the total production of CDW stands at about 52.1 million tons, while the total recovery of the material reaches 40.7 million tons. Hence, the percentage of CDW recovery is at 78.1%, which is above the 70% target set by the European directive.

The waste material deriving from the construction and demolition process, if specifically processed, can be reused as aggregates for the construction of new civil works. In the road pavement industry, CDW aggregates are already used in the formation of subgrades or for the production of asphalt mixtures, providing satisfactory and promising solutions (Ossa et al., 2016). Despite these encouraging results, the widespread use of recycled CDW aggregates is still hampered in Italy. One of the main reasons is the lack of confidence in the products derived from waste, combined with a poor knowledge of technical characteristics of the same. Moreover, low taxes on mining activities and landfills do not yet allow adequate competitiveness of recycled aggregates compared to virgin ones (Iacoboaea et al., 2019).

The recycling process of CDW aggregates is usually inexpensive and can bring high advantages like:

reduction of the amount of waste destined to landfills;

reduction of extraction and consumption (preservation) of non-renewable primary (and natural) resources;

cost reduction, since waste materials are cheaper compared to virgin aggregate.

An improvement in the environmental sustainability of pavement construction will be possible only if complemented by scientific and technological support aimed at demonstrating the feasibility of employing CDW materials. The research activities described in this thesis are part of the INTREC (Innovative technologies for recycled aggregates from construction and demolition waste in road construction) Project. This study aims at developing stabilized granular mixtures with recycled aggregates for the formation of subbase layers of road pavements. The study adds a contribution to the development of a wider knowledge on the use of recycled aggregates stabilised with alternative binders and their in-situ performances.

1.1. State of the art

CDW is generated by construction and demolition activities of buildings, civil works or road infrastructures. CDW is a strongly heterogeneous material whose composition depends on multiple factors such as (i) local construction types and techniques, (ii) raw materials and (iii) the construction products locally available. The composition of CDW mainly consists of concrete, bricks, bituminous mixtures, natural aggregates and excavated soil. Moreover, undesired materials such as metals, plastic, wood and glass can also be present.

This material can be processed to create CDW recycled aggregates. The transformation of a waste product into a commercial one is obtained through analysis, treating and by a third-parties control process. If performed correctly, these steps lead to the CE marking of the recycled aggregate, which is a fundamental requirement for its placing on the market. According to the EU regulation, the suitability and homogeneity of the material are guaranteed when it is provided with the CE marking (EU regulation n. 305/2011).

CDW recycled granular material is already used as filling material in the road embankments formation (Zhang et al., 2020), and the construction of unbound pavement layers for low-traffic roads (Pourkhorshidi et al., 2020; Arulrajah et al., 2013a). Many studies advocated that the mechanical properties of mixed recycled aggregates, such as resilient modulus (RM) and California Bearing Ratio (CBR) are comparable to virgin aggregates when used in unbound layers of road pavements. (Leite et al., 2011; Arulrajah et al., 2013a).

As well as natural aggregates, also in the case of CDW aggregates, mechanical properties can be improved by recurring to stabilization techniques (Beja et al., 2020; Del Rey et al., 2016). Stabilization can be performed with traditional binders as lime and cement. Taha et al. (2002) and Puppala et al. (2011) demonstrated that the mechanical properties of recycled aggregates stabilized mixtures increase remarkably with respect to unstabilised mixtures. Traditional binders like Portland cement are expensive and their production process is responsible for the production of a huge amount of CO_2 (Zhang et al. 2014). A valid alternative to the stabilization with traditional binders is the use of by-products coming from industrial processes like fly-ash, cement kiln dust, or the stabilization through alkaline activation.

1.1.1. CDW stabilized with non-traditional binders

The use of recycled aggregates in substitution of the natural ones aims at reducing the environmental impact of road constructions. The same goal has to be pursued when non-traditional binders are considered. The environmental sustainability of a binder can be evaluated in terms of local availability, transportation costs and CO_2 emissions. The sustainability of a binder must be evaluated also in terms of mechanical properties, a reasonably limited amount of binder has to provide the mixture with sufficient strength over time. In this context, the research on new solutions in the field of binders is becoming of pivotal role.

Interesting results have been achieved with the stabilisation of CDW aggregates through alkaline activation of fly ash (FA) or blast furnace (BF). Mohammadinia et al. (2016) assessed the suitability of this solution when employed in base and subbase layers of road pavements. The CDW aggregates were composed of recycled asphalt product (RAP), crushed bricks (CB) and recycled concrete aggregates (RCA). The stabilisation was obtained by mixing the CDW aggregates with different combinations of FA or BF and by adding different percentages of an alkaline solution to activate the chemical reactions. The values observed in the unconfined compression test (UCS) showed an improvement in mechanical strength proportional to the alkaline solution content.

Of particular interest in terms of environmental sustainability is the study of Bassani et al. (2019), which demonstrated that CDW fine powders containing crushed concrete and ceramic material can react in an alkaline environment increasing in strength without the addition of external reactive precursors. In the study, the fine fraction of the granular mix was used to stabilize the coarse aggregates thanks to the reaction induced by the alkaline environment. In the formation of stabilized subbase layers made of CDW aggregates, this solution can be advantageous from an economical and environmental point of view since it does not require the use of any conventional binder and promote the innovative use of CDW aggregates with adequate mechanical properties comparable to those of traditional cement-stabilized natural granular materials.

1.1.2. Field performance of cement stabilized CDW aggregates

Interesting results have been observed with the use of recycled aggregates in road pavements.

The experimental study of Agrela et al. (2012) involved the construction of three trial sections 300 m long with a pavement structure composed of a 30 cm-thick cement-stabilized soil as subgrade, 20 cm of cement-treated subbase (with 3% of CEM II/B) and a top bituminous mixture of 15 cm layer. The three sections were identical in composition except for the subbase layer in which were used natural aggregates (NA) in the first section, in the second section were used a mix of recycled aggregates composed of RCA and CB in equal proportions (MixRA-15), in the last section were used CC and CM with a proportion of 34 % and 64 % respectively (MixRA-22). On the subbase layer were performed impact deflectometer tests after 28 days, a 67 kN load was applied on a 450 mm diameter plate. The surface deflection of the cement-treated recycled aggregates sub-base (both MixRA-15 and MixRA-22) was equal to 0.10 mm, while the section with NA had a mean deflection equal to 0.21 mm on its surface. Moreover, the 28 days unconfined compressive strength performed on cored samples, showed a mean value of 4.17 MPa in the section with natural aggregates, 4.51 MPa in the MixRA-15 section, and 4.25 MPa in the MixRA-22 section. These results confirm that recycled aggregates in stabilised subbase layers can reach similar or higher performances with respect to the natural ones, in terms of stiffness and strength.

Similarly, Perez et al. (2013) investigated the mechanical response of two different road sections, in which the subgrade layer was the same for both, while the first subbase consisted of a 21 cm-thick cement-treated recycled concrete aggregate layer (CT-RCA), and the second one consisted of a cement-treated natural aggregate layer (CT-NA) of the same thickness. In both cases, the mixtures were stabilised with 3.5 % of CEM II/A. The surface deflection was measured through an impact deflectometer by applying a 67 kN load on a 450 mm diameter plate. The results showed that a deflection equal to 0.317 mm was obtained on the CT-RCA layer and 0.398 mm on the CT-NA. Also in this case, the recycled aggregates stabilised mixture reported a higher value of stiffness with respect to the natural aggregates mixture.

1.2. Objectives

The use of recycled materials such as aggregates deriving from CDW, replacing virgin natural resources, is increasing in popularity in road construction. Several studies have shown that CDW aggregates can replace natural mixtures in the subgrade and subbase layers of the pavement. Although several successful applications are documented, recycled materials are still viewed with

some distrust. This can be related to several reasons such as the large availability of virgin natural resources, the reduced durability concerning the degradation phenomena produced by traffic and the environment, and to a lack of scientific knowledge which brings distrust from the authorities (Iacoboaea et al., 2019).

The experimental investigation described in this thesis partly covers the gap in knowledge on the properties of these materials.

INTREC (Innovative Technologies for RECycled aggregates from construction and demolition waste in road constructions) project aims at promoting the reuse of this alternative source of aggregate through the investigation of stabilized and non-stabilized mixtures. The objective of INTREC is to increase the economic and environmental sustainability of road constructions. The project plans at developing stabilized granular mixtures with recycled aggregates for the formation of sustainable road subbase layers. The project is organized into three Work Packages (WP). WP1 concerns the laboratory study and experimental characterization of innovative stabilized mixtures, obtained from natural and recycled aggregates. WP1 includes the design, in terms of geometry and operation, of an experimental field trial (to be developed in WP2). WP2 aims to test the mechanical performance of the innovative materials at a real scale. During WP2, the mechanical performance will be tested in the experimental site, and the environmental and economic sustainability of the materials will be monitored and evaluated. Finally, in WP3 an experimental road section will be built. In WP3, structural and environmental investigations will be carried out to demonstrate the applicability of the technological solutions of the INTREC project.

The experimental investigation of this thesis is included in the WP1 of INTREC, and the main objectives follow:

the laboratory study of the CDW granular mixtures stabilised with non-traditional binders (paragraph **Errore. L'origine riferimento non è stata trovata.**) through optimum water content, the maximum dry density, the resilient modulus, the UCS and the indirect tensile strength (ITS) determinations;

the selection of the materials to be investigated in real-scale;

the implementation of preliminary site operation in order to test the equipment (lightweight deflectometer) evaluating the sensibility of the measured dynamic modulus with respect to the variation of the applied stress and to the different levels of compaction, and testing the procedures in view of the experimental field trial;

the design of the experimental field trial section, which included the geometry and structural design, the material quantity estimation, the schedule definition and the programming of the performance monitoring system.

2.1. Experimental design

In line with the objectives, the experimental plan was divided into two stages: (i) the laboratory tests and (ii) the design of the experimental field trial. In the first stage (laboratory test), the composition of the mixtures was defined and their mechanical properties were investigated. In the second stage (experimental field trial design), the geometric characteristics of the site were designed and the in-situ investigations were planned. In addition, it was developed a preliminary testing box in which the equipment and procedures for the field activities of WP2 were tested.

2.1.1. Laboratory tests

The laboratory investigation aimed at determining the mechanical characteristics of stabilized CDW mixtures with different types of binders. In order to compact specimens at their maximum densification, the optimum water content and the maximum dry density as per the Proctor method. The mechanical characterisation of the mixtures was focused on the determination of the RM and UCS after 7 and 28 days of curing, and ITS after 7 days of curing only. The analysis of laboratory results allowed to select the mixtures to be used in the field trial test. Since the length of the testing site was defined and referring to the mechanical properties determined during the previous stage, three innovative mixtures, two unbound mixtures and two reference mixtures were selected.

2.1.2. Field trial test design

The field trial test is aimed at investigating the in-situ properties of the stabilised and unbound mixtures that were selected in the previous stage of the study. The mixtures will be employed as subbase layer of the field trial road section. In this thesis, the design of the field trial and the programming of the activities necessary to investigate the properties of the examined materials was carried out. The geometrical design of the road was provided by Cavit, while the thickness of the pavement layers was determined through a structural analysis employing a mechanical model. The field tests to be developed on-site were defined on the basis of national prescriptions such as the CIRS regulations (CIRS *e Ministero delle Infrastrutture e dei Trasporti, 2° edizione*) and consulting reliable guidelines such as the "*Quaderni tecnici*" of ANAS (ANAS 2019). During the execution of the preliminary field trial operations, it was possible to test equipment and methods to be implemented in the field trial, moreover, the sensitivity of the LDW device was assessed. The material quantities necessary to build the field trial were determined on the basis of

the experimental site dimensions and the thickness of the pavement layers established in the structural analysis. The final stage was dedicated to the scheduling of construction operations.

The logical scheme of the experimental site design is shown in Figure 1.

Figure 1: Experimental design, conceptual scheme of the experimental site design

2.2. Materials

2.2.1. Natural and recycled aggregates

Recycled aggregates from CDW were provided by Cavit S.p.A. (La Loggia, Torino). The recycling plant has a production capacity of 250,000 tons per year. The recycling process begins with the recovery and collection of construction waste from civil works. The material is mainly composed of concrete, bricks, bituminous mixtures, natural aggregates and excavation soil, but metal materials, plastics, wood and glass are also present in minimal quantities. As the CDW

arrives at the Cavit plant, it must be selected. At first, it is transported to a control station where wood, plastic sheets and iron elements are separated. Subsequently, the material is sieved and the components that exceed 40 mm in size are separated and sent to an additional crushing process. The finest fraction is subjected to mud removal, then, air blowers allow eliminating the lightest material such as plastics. In this phase also the metallic scraps are removed with a magnetic device. At the end, the material is sieved and separated into different piles depending on the grain sizes (0-10, 0-8, 8-40 and 40-100 mm). The materials are marked with CE certification required by law. In this study, only the material passing through 25 mm was used, since larger particles are unsuitable to prepare cylindrical samples with a diameter of 100 mm.

In the case of natural aggregates, the material was provided by Cave Germaire (Carmagnola, Italy); grains passing at 25 mm was used also in this case.

Table 1 reports the physical parameters of the aggregates.

PARAMETER	NATURAL	CDW
SHAPE INDEX [%]	13	14
FLATTENING INDEX [%]	14	12
DENSITY [kg/m ³]	2669	2597
ABSORPTION [%]	0.9	3.7

2.2.2. Binders

-

In the study, the attention was focused on innovative and environmentally sustainable binders. To provide a reliable comparison of the mechanical properties, traditional binders like Portland type II cement were used. The characteristics of the binders used are reported as follows.

CEMENT

Cements were provided by Holcim S.p.A. During the experimental investigation, the following cements were employed:

CEM II/B-LL 32,5 R: Portland limestone cement, compliant with regulations UNI EN 197-1:2011 (*Ente nazionale italiano di unificazione*, 2011), with 67-79% of clinker and 21-35% of limestone. Its density is equal to 2930 kg/m³ (Holcim S.p.A. 2020a);

CEM IV/B: following the quantities defined by the reference standard UNI EN 197-1:2011 (*Ente nazionale italiano di unificazione,* 2011), contains from 45% to 64% of clinker and from 36% to

55% of calcined clay as an industrial pozzolan, with minor components in quantities not exceeding 5%, the density was assumed to be equal to the one of CEM II/B, 2930 kg/m³; HYBRID CEMENT: mixture obtained by mixing 50% by weight of CEM IV/B and 50% of calcined clay, the density was assumed to be equal to the one of CEM II/B, 2930 kg/m³.

ALKALI-ACTIVATE CDW FINES

As reported in paragraph 1.1.1, stabilized CDW aggregate mixtures can be stabilised without the addition of traditional binders. The stabilization is possible thanks to the addition of alkaline liquids that activate chemical binding reactions between aluminosilicates and alkaline metal silicates present both in the fine CDW fine fraction and in the alkaline solution used. The alkaline solution is composed of 20% by weight of hydrated sodium hydroxide (NaOH) and 80% by weight of hydrated sodium silicate (Na₂SiO₃).

In the study, three alkaline solutions (AS) were adopted to trigger the alkali-activation of CDW fines:

AS1: aqueous solution obtained in the lab by mixing 20% by weight of 50%-concentrated sodium hydroxide (NaOH) solution and 80% by weight of sodium silicate (38/40 Bé R3.3) (Na₂SiO₃); AS2: aqueous solution composed of sodium silicate (44 Bé R1.65) present in a ratio SiO₂/Na₂O of about 1.65, the liquid is obtained by a hydrothermal process performed in the Ingessil S.r.l. plant;

AS3: is a solution identical to the AS2 one but with the addition of a surfactant to reduce the viscosity.

BONDAFIX FH 130

In the investigation, a commercial binder named Bondafix FH 130 (Barzaghi s.r.l.) was investigated for the production of stabilized CDW aggregates. It is a composite agglomerating polymer of natural origin. It is a powder with a density equal to 1000-1100 kg/m³ (Barzaghi s.r.l. 2020); when mixed with water it provides binding properties. Table 2 reports the characteristics summary of the binders.

BINDER	DENSITY [kg/m ³]	COMPOSITION
CEM II/B-LL 32,5 R	2930	67-79% clinker, 21-35% limestone

Table 2:	Character	ristics o	of the	binders
----------	-----------	-----------	--------	---------

2.2.3. Mixtures

BLENDS WITH NATURAL AGGREGATES

The properties of natural aggregates mixtures were investigated in a previous study by Avellino and Gugliotta (2021). In this study, these mixtures were considered for comparison purposes.

In particular, mixtures stabilised with 3 % by weight of CEM II/B, denominated as NAT+3CEM-II/B, and the unbound natural aggregate denominated as "NAT and water" were considered. Both of the mixtures present an Optimal Moisture Content (OMC) equal to 6.5 %, and the Maximum Dry Density (MDD) is 2.253 Mg/m³ and 2.248 Mg/m³ for the stabilised mixture and the unbound one respectively. These materials were employed as a reference to compare the mechanical properties of the mixtures containing recycled aggregates.

BLENDS WITH CDW AGGREGATES

Regarding the Bondafix binder, three solutions containing 4 %, 8 % and 12 % by weight of binder were tested. The blends were named respectively CDW+4BF, CDW+8BF and CDW+12BF.

Concerning the mixtures stabilised with alkali-activated CDW fines, three mixtures combinations were investigated. Previous studies defined the properties of the mixtures stabilised with AS1 (Avellino and Gugliotta, 2021), the OMC was found to be 8.5 %, which corresponds to an MDD of 2.155 Mg/m³. This mixture was denominated CDW+AS1. The same OMC and MMD were assumed for the mixtures stabilised with AS2, which were denominated CDW+AS2. In the case of AS3, the solution containing surfactant, OMC and MDD were determined during this study, the denomination for this blend is CDW+AS3.

To compare the mechanical properties between the mixtures stabilised with traditional and non-traditional binders, the one stabilised with 3% by weight of CEM II/B (CDW+3CEM-II/B) showed an OMC equal to 8.5% and an MDD of 2.119 Mg/m³ (Avellino and Gugliotta 2021).

Two mixtures containing CEM IV/B were investigated, the first one was denominated as CDW+3CEM-IV/B, it contains 3% by weight of CEM IV/B, the OMC and the MDD were assumed to be the same as for the mixture CDW+3CEM-II/B (Avellino and Gugliotta 2021). The second one contains 3% by weight of "hybrid" cement (50% CEM IV/B and 50% calcinated clay), also in this case the OMC and the MDD were assumed to be the same as for the mixtures CDW+3CEM-II/B, the blends were denominated as CDW+3IB.

Finally, the unbound granular mixture with OMC equal to 8.5% and an MDD of 2.121 Mg/m³ (Avellino and Gugliotta 2021). The mixture was denominated "CDW and water" was considered. Table 3 resumes the characteristics of the mixtures.

MIXTURE NAME	AGGREGATE	BINDER	BINDER %
NAT and water *	NAT	-	-
CDW and water *	CDW	-	-
NAT+3CEM-II/B *	NAT	CEM II/B	3
CDW+3CEM-II/B *	CDW	CEM II/B	3
CDW+3CEM-IV/B	CDW	CEM IV/B	3
CDW+3IB	CDW	HYBRID CEMENT	3
CDW+AS1 *	CDW	CDW fines + AS1	8.5 AS1
CDW+AS2	CDW	CDW fines + AS2	8.5 AS2
CDW+AS3	CDW	CDW fines + AS3	4-6-8-8.5-10-12 AS3
CDW+4BF	CDW	Bondafix	4
CDW+8BF	CDW	Bondafix	8
CDW+12BF	CDW	Bondafix	12

Table 3: Studied mixtures (studied by Avellino and Gugliotta (2021)).

2.3. Methods – Laboratory tests

This paragraph describes the methods adopted to perform the laboratory tests on mixtures. A specific Proctor study to determine OMC and MDD was performed. The Optimal Moisture Content (OMC) and the Maximum Dry Density (MDD) were used as inputs in the recipes used to mix the constituents of mixtures and prepare the samples through the gyratory shear compactor.

In addition, during the compaction the workability parameters were recorded. The mechanical properties of stabilized mixtures were evaluated in terms of Resilient Modulus (RM) through the cyclic triaxial test and compressive and tensile strengths in the Unconfined Compressions Strength (UCS) on slim samples and the Indirect Tensile Strength (ITS) tests on stubby samples.

2.3.1. Proctor study

The Proctor study allows investigating the degree of compaction that a granular mixture (or a soil) can achieve when a specific water content is added. The objective of the test is to determine the OMC that induces the MDD of the mixture ($\gamma_{d, Max}$). According to UNI EN 13286-2 (2010), the modified procedure was adopted (mould type B, hammer mass of 4.5 kg and 56 blows per layer). In Figure 2 the equipment used is shown.

Figure 2: Proctor compaction machinery

The procedure starts with the preparation of the mixture in a metallic bowl, which is then sealed with a plastic coat and left to rest. After, the first layer of material is laid in the Proctor mould. The compaction consists of 56 blows per layer. For each blow, the mass is first lifted and then fallen at an elevation of 457 mm above the sample. At the end of the compaction, five uniform layers are obtained in a sample. The material contained in the mould of known volume is weighed and dried to estimate the MDD and through the measurement of the effective water content. Figure 3 shows some significant steps of the test.

Figure 3: (a) Preparation of the mixture; (b) Compaction; (c) Mass measurement operations

The dry density is obtained from the following relation:

$$\gamma_d = \frac{\gamma_w}{(1+w)} \left[kg/m^3 \right]$$

where:

 $\gamma_{w} = \frac{Wet \ sample \ mass}{sample \ volume} \ [kg/m^{3}]: \ wet \ density$ $w = \frac{Water \ mass}{Dry \ solid \ mass} \ [\%]: \ water \ content$

By varying the water content (w) in the mixture, it is possible to draw the Proctor curve and determine the maximum dry density. Table 4 lists the stabilized mixture undergone to Proctor study in the INTREC project.

Aggregate type	Binder	W [%]	Mixture name				
	Unbound	2 - 4 - 6 - 6.6 - 8 - 10 %	NAT and water *				
NAT	2% CEM II/B	2 - 4 - 6 - 7 - 8 - 10 %	NAT+2CEM-II/B *

Table 4: Mixtures tested with Proctor compaction

2.3.2. Specimen preparation by the gyratory shear compactor

The gyratory shear compactor allows to produce cylindrical samples of different sizes and to obtain the workability parameters. During compaction, the actual height of the specimen is recorded for each gyration in order to determine the workability parameters: self-compaction (C_1) and workability (k). The compaction degree (C_n) is calculated at every gyration, and it is defined as the ratio between the density of the material and the maximum density achievable (measured with the Proctor study). C_1 and k describe the compaction degree as a function of the number of cycles (Figure 4). The compaction ends when the layer of material reaches the predefined height or when the maximum number of gyrations is reached.

Figure 4: Workability curve and parameters.

where:

 C_n = Degree of compaction at the nth cycle expressed as a percentage;

 C_1 = Self-compaction, compaction of the material due to its weight;

k = Workability of the mixture identified by the angular coefficient of the compaction curve;

n = Number of revolutions.

Two different sets of samples were prepared: (i) slender samples of 186 mm height and 100 mm of diameter were produced for both UCS tests and RM, and (ii) stubby samples 100 mm height and 100 mm of diameter for indirect tensile tests. Specimens were compacted in different layers to obtain a uniform compaction along the entire height. The slender samples were compacted into three layers of 62 mm in height each, while the stubby ones in two layers of 55 mm and 45 mm height. After compaction, the specimens were cured at room temperature in humid conditions (RH > 95%), Figure 5 shows the steps of the specimen preparation.

Figure 5:(a) Mixture preparation; (b) Sample sealing; (c) Box for curing in a humid environment.

Table 5 reports the parameters adopted for the preparation of slander samples, while Table 6 reports the parameters adopted in the preparation of stubby samples of the mixtures stabilised with Bondafix. In Table 7 the same parameters used in the preparation of stubby samples for the mixtures stabilised with hybrid cement and alkali-activated CDW fines are shown. In Table 8 the total number of samples produced for each mixture type is reported.

2.3.3. Cyclic triaxial test

Cyclic triaxial test is used to determine the RM of a granular unbound or stabilized mixture. The test was carried out by means of the Nottingham Asphalt Tester, applying repeated pulse loads to the specimen. The cyclic triaxial test was performed according to AASHTO T307-99:2007 (AASHTO 2007).

The RM corresponds to the stiffness of non-linear granular materials, and it is used as an input parameter for the structural design of road pavements. Hence, RM depends on the stress state to which the granular material is subjected, and the test is performed in a triaxial chamber under different stress conditions. The resilient modulus is defined as the ratio between the deviatoric stress and the vertical recovered deformation:

$$RM = \frac{\sigma_d}{\varepsilon_r}$$

where:

 $\sigma_d = \sigma_1 - \sigma_3$ is the deviatoric stress;

 σ_1 and σ_3 are the principal stress in the vertical and radial direction respectively;

 ε_r is the vertical resilient (recovered) strain.

Due to the stress-dependency of RM, the AASHTO T307 suggests measuring it in fifteen different loading conditions as per those reported in Table 9. During each loading sequence, the material is subjected to a constant radial pressure (σ_3), while the vertical pressure (σ_1) is applied with periodic pulses of 0.1 s of load and 0.9 s of rest. The first loading sequence, composed of a thousand load cycles, allows to pre-conditionate the sample. The following fifteen sequences are composed of one hundred cycles.

Sequence	Confining Pressure, S ₃		Max. Axial Stress, S _{max}		Cyclic Stress, S _{cyclic}		Constant Stress, 0.1S _{max}		No. of Load

Table 9: Cyclic load sequences (AASHTO T307)

Experimental results of RM testing were fitted with the M-EPDG (Mechanistic-Empirical Pavement Design Guide) model:

$$RM = k_1 \cdot p_a \cdot \left(\frac{\theta}{p_a}\right)^{k_2} \cdot \left(\frac{\tau_{oct}}{p_a} + 1\right)^{k_3}$$

where:

RM = Resilient modulus, in *MPa*;

 k_i = Regression parameters;

 p_a = Atmospheric pressure, 0.1013 *MPa*;

 θ = Bulk stress = $\sigma_1 + \sigma_2 + \sigma_3$

 τ_{oct} = Octahedral stress, in *MPa*, under axial symmetry conditions, equal to:

$$\tau_{oct} = \frac{\sqrt{2}}{3} \cdot \sigma_d = \frac{\sqrt{2}}{3} \cdot |\sigma_1 - \sigma_3|$$

In order to obtain the regression coefficients k_i , the least-squares method was applied in an Excel spreadsheet. The goodness of the fitting was evaluated by means of the following parameters:

 R^2 = Coefficient of determination;

 R_{adj}^2 = Adjusted coefficient of determination, which takes into account the number of variables in the model;

 S_e/S_y = Ratio between the standard estimation error and the standard deviation.

The R^2 parameter is considered as good as much it gets closer to one, while the S_e/S_y parameter is as good as much as it is close to zero, Table 10 provides a reference in the estimation of the goodness.

CRITERIA	R ²	Se/Sy		
Excellent	> 0.90	< 0.350		
Good	0.70-0.89	0.36-0.55		
Fair	0.40-0.69	0.56-0.75		
Poor	0.20-0.39	0.76-0.90		
Very Poor	< 0.19	> 0.90		

Table 10: Evaluation of the goodness of the fitting parameters (Witczak et al. 2002)

Figure 6 reports the NAT apparatus and the steps performed during the triaxial test

Figure 6: (a) Nottingham asphalt tester (NAT) during the testing of a sample; (b) Equipment; (c) Sample preparation.

2.3.4. Unconfined compression strength (UCS)

The UCS test defines the maximum compressive stress that the specimen can withstand in the absence of lateral confinement. The test was performed according to the UNI EN 13286-41:2006 (Ente Nazionale Italiano di Unificazione 2006a).

The test was performed by applying a constant displacement rate of 0.5 mm/min on the specimen. The load cell, with a capacity of 50 kN, recorded at the frequency of 5 Hz the applied force, while a strain transducer evaluated the vertical deformation.

The stress-strain curve recorded during the test allowed to obtain several parameters:

- σ_{max}: is the maximum strength that the sample exhibits under a compression state of stress, it is obtained by dividing the maximum force applied by the area of the specimen section, in MPa;
- E_{sec} : is the secant elastic modulus, which is identified by the slope of the straight line passing through the initial deformation and the maximum stress, in MPa;
- E_{tan} : is the tangent elastic modulus, which is obtained by evaluating the slope of the stress-strain curve in its linear part, in MPa.
- T: is the toughness (energy at failure), graphically can be defined as the area under the stress-strain curve, in kPa mm/mm.

The maximum compressive strength and the two elastic moduli were determined after 7 and 28 days of curing. Figure 7 shows the stress-strain curve and the parameters obtained from the UCS test.

Figure 7: Graphical representation of the UCS parameters.

In the elastic phase, the stresses increase with a linear dependence with respect to the strains. As the applied stress approaches the maximum value, the plastic strains become more evident, and the stress-strain curve shows a non-linear behaviour until it reaches the peak (σ_{Max}). At this point, cracks are visible on the sample which is not able to support an additional load (Figure 8).

After the test, the sample is weighed and dried at 105 °C to determine the water content in the material.

Figure 8: Examples of satisfactory failures of specimens UNI EN 13286-41

Figure 9 shows the UCS testing equipment and the execution of the test.

Figure 9: (a)UCS test equipment; (b) Cracked sample during the test.

2.3.5. Indirect tensile strength (ITS)

Indirect tensile strength (ITS) test was carried out according to the standard UNI EN 13286-42 (2006b). The test was performed on cylindrical samples of 100 mm in diameter and height (Figure 10) after 7 days of curing. The ITS is a static test performed at the displacement rate of 0.5 mm/min. The indirect tensile stress is then obtained from the equation:

$$\sigma_t = \frac{2 P}{\pi d h}$$

where:

 σ_t = Indirect tensile strength, in *MPa*

d = Diameter of the specimen, in mm;

h = Height of the specimen, in *mm*;

P = Maximum applied force, in *N*.

Figure 10 : (a) ITS test machinery; (b) Crack in the sample after the test

2.4. Methods – Field investigation

2.4.1. Light weight deflectometer (LWD) test

The Light Weight Deflectometer (LWD) equipment consists of a falling weight, a dumper device at the bottom and a loading plate, and a series of sensors to measure the load and the vertical displacement of the loading plate. The mass is dropped from a predetermined height on the circular loading plate, and a load impulse is transmitted to the pavement top. The sensors measure the applied load impulse intensity and shape, and the deflections of the plate in function of time. The load impulse is measured through a load cell and the deflection under the centre of the plate is measured with a geophone. Two additional geophones may be added to measure the deflection profile, and then calculate the stiffness of the layered systems. In the assessment carried out in this study, the LWD was used with three geophones. The test allows to determine the dynamic surface modulus, the stiffness modulus of pavement layers and the degree of compaction of soils. These parameters are universally assumed as fundamental parameters in the final evaluation of the performance of road construction. The tests were conducted according to the American standard ASTM E2583–07 (2015).

The LWD employed during field trials is the Dynatest 3032, whose characteristics follows:

• main unit with integral load cell and central deflection sensor;

- 300 mm diameter plate and a rubber pad of the same size; this unit includes also 100, 150, and 200 mm plates;
- two additional geophones;
- a guide shaft;
- buffer pads;
- 10 kg weight plus two additional 5 kg weights.

Figure 11 shows a schematic representation of the LWD.

Figure 11: LWD description

According to the standard ASTM E2583–07 and the supplier manual, the first step is to fix the dimensions of the load plate and the value of the height from which the weight is dropped, to define the applied stress. The applied pressure is defined as the maximum force divided by the plate area. Varying the weight of the falling mass, the diameter of the load plate, the drop height and the buffer configuration, the user can control both the intensity and the duration of the stressing pulse. The weight is lifted and fixed to the required height, and then released to impart the impulse. Generally, the first 3 falls are used to ensure good contact between the plate and the surface and were then excluded from the computation.

The surface modulus at the centre of the plate is determined according to Boussinesq theory:

$$E_0 = \frac{f \cdot (1 - v^2) \cdot \sigma_0 \cdot r}{d_0}$$

where:

 E_0 = Surface modulus, in *MPa*;

- f = Plate stiffness factor (2 for uniform distribution, $\pi/2$ for rigid plate);
- ν = Poisson ratio of the soil;
- σ_0 = Maximum contact pressure, in *MPa*;
- r = Plate radius, in mm;
- d_0 = Maximum deflection at the centre of the plate, in *mm*.

The surface modulus represents a composite value for the pavement rather than a single layer. The measured deflection depends on the response of the material inside the displacement basin of influence, i.e., the portion of soil in which the stresses are significant. The depth of this basin depends on the plate diameter and on the stiffnes of the soil.

2.4.2. Plate load test

The plate load test as per the Italian standard BU CNR 146/92 allows to determine the deformation modulus (M_d). The deformation modulus represents a conventional measure of the bearing capacity of pavements, it is determined through a load test with a circular plate and it is expressed as per the following relation:

$$M_d = \frac{\Delta P}{\Delta D} \cdot \varphi \ [MPa]$$

where:

- $\Delta P[MPa] =$ Increase in the pressure on the rigid circular plate;
- φ [mm] = Diameter of the circular plate (300 mm);
- $\Delta D [mm] =$ Increase in the settlement of the loaded layer.

The test requires a contrast which is generally constituted of a truck or an excavator. During the test, the plate is placed on a thin layer of sand that serves to even out the support surface, then, a preload of $0.02 \ MPa$ is applied. When the settlement of the plate is completed (i.e., the difference between two readings at a distance of one minute < $0.02 \ mm$), a $0.05 \ MPa$ stress is applied and the first displacement is measured. Further measurements are recorded applying successive increments of $0.05 \ MPa$ until reaching $0.35 \ MPa$ on the top of a subgrade, or increments of $0.10 \ MPa$ until reaching $0.35 \ MPa$ on the top of a subgrade.

 M_d is determined by posing ΔP equal to 0,1 *MPa* and determining ΔD considering the interval of ΔP between 0,05 and 0,15 *MPa* for subgrades and embankments, or between 0,15 e 0,25 *MPa* for subbases.

After this procedure, the plate is unloaded and second moduli, M'_d is evaluated with the same modality presented before. The ratio between M_d and M'_d is called compaction degree. The compaction degree is as close to 1 as the material is compacted.

2.4.3. In-place density with sand-cone test:

The in-place density is determined with the sand-cone test following the standard ASTM D 1556-00 (2000). The apparatus used is reported in Figure 12.

Figure 12: In-place density apparatus (ASTM D 1556-00)

The test uses sand with known density to determine the in-situ density of a soil. The sand is inserted in a hand-excavated hole, knowing the density and the mass of the sand, the volume of the hole is calculated. The masa and water content of the removed soil are measured, therefore the wet and dry density can be computed.

The dry density is obtained as follows:

Hole volume: $V = (M_1 - M_2)/\rho_1$

where:

- V: Test hole volume [cm³];
- M₁: Mass of sand used to fill the test hole, funnel and base plate [g];
- M₂: Mass of sand used to fill the funnel and base plate [g];
- ρ_1 : Bulk density of sand $\left[\frac{g}{\text{cm}^3}\right]$.
- Dry mass of material removed from the test hole: $M_4 = 100 M_3/(w + 100)$
- w: Water content of the material removed from the hole;
- M₃: Wet mass of material removed from the test hole [*g*];
- M₄: Dry mass of the material removed from the test hole [g].
- Wet and dry in-situ density of the tested material: $\rho_w = M_3/V$ $\rho_d = M_4/V$
- $\rho_{\rm w}$: Wet density $[\frac{g}{{\rm cm}^3}]$;
- ρ_d : Dry density $[\frac{g}{cm^3}]$.
3. RESULTS AND DISCUSSION OF LABORATORY TESTS

In this section, the results obtained from the Proctor study, the workability parameters and the strength tests (UCS and ITS) on the studied mixtures are discussed. Moreover, these data are compared with the outcomes obtained during the previous stages of the INTREC project.

3.1. Proctor study

The Proctor test was performed on the three Bondafix stabilized mixtures (4, 8 and 12 % by weight), and on the alkali-activated CDW fines using AS3 stabilized mixture. Figure 13 compares the Proctor curve of the three Bondafix stabilized mixtures and the unstabilised CDW mixture.

Figure 13: Proctor curves for recycled aggregates stabilized with Bondafix.

The curves presented in Figure 13 approximate parabola arcs, for each of them, the peak is achieved with water content between 8 and 10%. It is worth noting that the OMC is similar for the three mixtures stabilised with Bondafix and for the unstabilised one. However, the OMC was identified as 8.5% for the stabilised mixtures too. The MDD was higher in the CDW aggregate than in the stabilised mixtures. In fact, the relevant quantity of Bondafix, which has a much lower density with respect to the aggregates (1000-1100 kg/m³) justify such results. As can be noted from Table 11, the MDD decreases as the binder content increases, while the OMC does not vary sensibly with the addition of the binder.

Mixture	γ _{d,Max} (kg/m³)
CDW+4BF	2047
CDW+8BF	2038
CDW+12BF	2031
CDW and water	2121

Figure 14 shows the comparison between the Proctor curves provided by the unstabilised CDW and the mixtures stabilised with alkali-activated fines of CDW aggregates (AS1 and AS3).

Figure 14: Proctor curves for recycled aggregates stabilized with AS1 and AS3.

The presence of the surfactant component in AS3 was expected to reduce the viscosity of the alkaline solution and to increase the compaction of the mixture. Contrary to what expected, CDW+AS3 reported a lower value of MDD compared to CDW+AS1. It can be noted also that the parabola provided by CDW+AS3 is less sharp if compared to CDW+AS1. The OMC was found to be 8.5% for CDW+AS1 and 8% for CDW+AS3. Also in this case, the OMC does not vary in a sensible way from the one of the unstabilised blend. The mixture stabilised with the original alkaline solution reported a higher maximum dry density with respect to the modified one as reported in Table 12.

Material	AS _{opt} (%)	γ _{d3max} (kg/m ³)
CDW + AS1	8.5	2155
CDW + AS3	8.0	2111

Table 12: Maximum dry densities and optimum liquid content (Alkaline solutions)

3.2. Workability

The parameters C_1 and k were computed for each sample, Table 13 reports the averaged values for each mixture type and the relative standard deviations.

		CDW and water *	CDW + 4 BF	CDW + 8BF	CDW + 12BF	CDW + 3IB	CDW + AS1*	CDW + AS2	CDW + AS3

Tested samples		-	6	9	6	11	-	9	9
* tested by Ave	ellino and	Gugliotta	(2021)						

Table 13: Workability parameters

The values of the parameters K and C_1 are reported in the bar chart of Figure 15.

Figure 15: Average values of $C_1(a)$ and K(b) with the corresponding standard deviation * Tested by Avellino and Gugliotta (2021).

All the materials exhibit workability greater than 8.0 except for the mixture stabilised with "Hybrid" cement, which reported a value of 7.9. In the mixtures stabilised with 8% of Bondafix and in the one stabilized with alkali-activated CDW fines (AS2), k is above 9. Regarding the self-compaction (C_1), the mixtures stabilised with Bondafix reported an increasing value of the parameter corresponding to an increase in the binder content. The mixtures stabilised with "Hybrid" cement, alkali-activated CDW fines, and the unbound mixture reported a similar value of C_1 .

3.3. Cyclic triaxial test (Resilient modulus)

Figure 16-a and Figure 16-b represent the RM of mixtures stabilised with "hybrid" cement, Bondafix and CEM IV/B as a function of the first invariant I_1 , after 7 and 28 days of curing respectively.

Figure 16: RM at 7 days of curing (a) and at 28 days of curing (b), mixtures stabilised with "Hybrid" cement, Bondafix and CEM IV/B.* Unstabilised mixtures (CDW and NAT) tested by Avellino and Gugliotta (2021).

The stiffness of all the materials increases as the applied stress increase, in a logarithmic scale RM has a linear behaviour with respect to I₁. At 7 days of curing, considering a first invariant stress of 275 kPa, the resilient modulus ranges between 450 and 520 MPa for all the mixtures stabilised with Bondafix and "hybrid" cement, the mixture stabilised with CEM IV/B reported the highest value among all the tested mixtures (638 MPa). At 28 days of curing the mixtures reported a decrease in RM, in particular, CDW + 3IB exhibited a modulus equal to 283 MPa (evaluated at I₁= 275 kPa), corresponding to a reduction of 44% with respect to the 7 days-cured samples. The unbound materials reported a stiffness three to four times lower than the stabilised

mixtures evaluated at 7 days of curing, while at 28 days the difference becomes lower, two times for the mixtures containing Bondafix or "hybrid" cement, and three times for the one containing CEM IV/B.

In Figure 17 are represented the average values of RM of mixtures stabilised with alkaliactivated CDW fines as a function of the first invariant I₁, after 7 and 28 days of curing time respectively.

Figure 17: RM at 7 days of curing (a) and at 28 days of curing (b) for AS2 and AS3stabilised mixtures. *Tested by Avellino and Gugliotta (2021).

Concerning the mixtures stabilised with alkali-activated CDW fines, at 7 days, the mixture containing AS2 reported a RM 35% higher than those containing AS1 or AS3 (I₁= 275 MPa). After 28 days of curing, CDW + AS2 reported a reduction in RM of 25%, CDW + AS1 did not have significant variations. CDW + AS3 is the only mixture in which the stiffness was higher

after 28 days with respect to 7 days of curing, in this case the increment was 30%. In the case of the mixtures containing alkaline solution, the stabilised mixtures reported a stiffness three to four times higher than the unbound blends.

Table 14 reports the values of the K parameters of the M-EPDG model and the relative statistical accuracy.

Taking into account the statistical parameters R² and Se/Sy, according to the classification given in paragraph 2.3.3 (Witczak et al. 2002), all the models can be classified as excellent or good except for the mixture stabilised with CEM IV/B which was classified as fair.

According to the M-EPDG model, the k_1 parameter is directly proportional to RM, the parameter k_2 represents the susceptibility of RM to the variation of the bulk stress, and k3 describes the variation of RM as a function of the octahedral stress.

From Table 14 it is possible to notice that the value of K_1 is higher at 7 days than at 28 days of curing for all the mixtures except for CDW + AS3, this is in line with the reduction of RM with the curing time. The decrease of stiffness in the 28-days cured samples may be due to the wettening of the material during the curing stages, several studies highlighted the influence of moisture content over RM, in particular, Naji (2018) showed how the RM of granular material reduces if the moisture content increases. As reported in paragraph 2.3.2, the samples were cured in a humid environment, during this time the long-time cured samples may have reached a higher moisture content with respect to the 7-days cured ones.

 K_1 reaches the highest values (at 7 days) in the mixtures stabilised with CEM IV/B and AS2 (3824 and 3868 respectively), as these mixtures reported the highest stiffness. The reduction in RM of CDW + 3IB passing from 7 to 28 days of curing is visible also from the reduction of k_1 (from 3297 to 1522). Regarding the mixture stabilised with Bondafix, k_1 is close to 3300 for the mixtures containing 4 and 8 % of binder (at 7 days), while it decreases by 12 % in the mixture with 12 % of binder content. As expected the unbound mixtures reported the lowest value for k_1 .

Most of the mixtures reported a decreasing value of k_2 when passing from 7 to 28 days of curing, this implies a reduction in time of the sensibility of RM to the stress variation. The only exceptions are represented by the mixtures CDW + AS1 and CDW + AS3 which reported an increase of about 17 and 6 % respectively. The highest k_2 value was reported by the unbound recycled aggregates mixture (0.85) while the lower value was given by the mixture stabilised with 8 % of Bondafix after 28 days (0.27).

The k_3 parameter has increased with the curing time in all the mixtures except for CDW + AS3. For most of the mixtures, it was recorded an inversion of sign (negative to positive) passing from 7 to 28 days of curing, the exceptions are represented by the mixtures stabilised with AS1, AS3 and 12 % of bondafix.

3.4. Unconfined compression strength and indirect tensile strength

The average values of UCS at 7 and 28 days are reported in Figure 18.

Figure 19: ITS at 7 days with the corresponding standard deviation. * Tested by Avellino and Gugliotta (2021)

Regarding the mixtures stabilized with Bondafix, it is clear from the results on the compressive strength that the strength increases as the binder content increases, only the mixture stabilized with 4% of Bondafix reported a UCS value lower than 1 MPa. In general, the strength increases with the curing time in all the tested mixtures, at 28 days, all the stabilised mixtures reported a UCS higher than 1.6 MPa, an exception is represented by the mixtures stabilized with "hybrid" cement, which exhibits a strength of 1.41 MPa. The higher UCS is achieved by the reference mixture of natural aggregates stabilised with cement type II/B, which reported a UCS of 1.3 MPa at 28 days of curing. The mixture stabilised with 8% of Bondafix reported a UCS of 1.3 MPa at 7 days of curing, and an increase of 50% passing to 28 days of curing. CDW + AS2 exhibited good UCS, both at 7 and 28 days of curing the strength is close to 1.9 MPa. The mixture stabilised with the modified alkaline solution (AS3) reported a compressive strength of 1.56 MPa

at 7 days and an increase of over 40% at 28 days. Among the alkali-activated stabilised mixtures, CDW + AS1 reported the lowest UCS both for 7 and 28 days of curing (1.26 and 1.77 MPa respectively). CDW + 3IB reported the lowest compressive strength among the tested stabilised mixtures (around 1 MPa, comparable to CDW + 4BF). The unbound CDW mixture reported a UCS 20 to 50 times lower with respect to the stabilised ones.

The Italian technical specification of CIRS (*CIRS e Ministero delle Infrastrutture e dei Trasporti, 2° edizione*) set a minimum threshold value for the ITS at 7 days equal to 0.25 MPa for the mixtures of natural aggregates stabilised with cement. All the tested stabilised mixtures containing recycled aggregates achieve this requirement, except for CDW aggregates stabilized with 4% of Bondafix and 3% of "Hybrid" cement (missing 30% and 17% respectively, to reach the CIRS threshold). As for the UCS, also in the case of ITS, the mixtures stabilised with Bondafix reported an increasing strength with the binder content (0.19, 0.26 and 0.31 MPa for the mixtures containing 4, 8 and 12% of binder respectively). The highest value of ITS was achieved by the mixtures stabilised with alkaline solution, both CDW + AS1 and CDW + AS2 reached values of about 0.35 MPa, while the mixtures stabilised with AS3 and CDW fines showed an ITS of 0.29 MPa. The tensile strength of the unbound CDW is 25 times lower than the CIRS threshold.

The values of deformation at failure $\varepsilon(\sigma_{C,MAX})$, elastic modulus ($E_{T,C}$ and $E_{S,C}$) and toughness (T_c) obtained from data modelling are reported in Table 15.

Table 15: Average values of strain ($\varepsilon(\sigma_{C,MAX})$), tangent modulus ($E_{T,C}$), secant modulus ($E_{S,C}$) and Toughness (T_C) of mixtures subjected to UCS test.

Similarly to the compressive strength values, also the parameters reported in Table 15 show an improvement of the performances when passing from 7 to 28 days, the maximum strain reduces, the elastic modulus and the toughness increase. An exception is represented by the mixtures containing AS2 were, passing from 7 to 28 days of curing both the tangent and secant elastic modulus decrease of about 5%.

In the 28 days cured samples the mixture stabilised with 8% of Bondafix reported an increase of 108% and 119% in the tangent and secant modulus respectively with respect to the 7 days cured ones. The CDW + 3IB reported an increase of 25% in the tangent modulus and 38% in the secant modulus. The mixture containing AS3 reported the highest increase in tangent modulus (136%) and an increment of 61% in the secant modulus.

The preliminary field trial was conceived to assess the procedures of the on-site tests to be performed during the field trial (plate load test, sand cone density and LWD measurements) and to investigate the sensibility of the LWD apparatus with respect to the variation of the input parameters such as plate diameter, drop height and impact mass. In addition, the sensitivity of the LWD device was tested on granular materials with different compaction degrees.

In order to achieve these goals, the preliminary field trial operations were divided into two stages, an LWD test simulation performed in the laboratory and an on-site test performed on a multi-layer granular material.

4.1. LWD test simulation

The capability of the device to detect the non-linear relationship between applied vertical stress and the dynamic modulus of the soil was assessed in this stage, by varying the device settings. To this purpose, a granular material layer was specifically produced and compacted in a PVC box. The layer consisted of a 25 cm-height unbound "CDW and water" mixture. The 25 cm of height were assumed to be sufficient to simulate the measurements on a homogeneous single layer with all the plate diameters available. In order to achieve sufficient homogeneity, the material was laid and compacted into three 8.3 cm-thick layers.

In Table 16 are reported the parameters necessary to produce the homogeneous layer.

Density									
$\gamma \mathbf{w}_{\mathrm{Max}}$	[kg/m ³]	2301							
$\gamma \mathbf{w}$ 85%	[kg/m ³]	1956							
Dimensions									
а	[m]	0.57							
b	[m]	0.37							
h	[m]	0.25							
Volume	[m ³]	0.053							
	Weight								
Total	[kg]	103.1							
Layer	[kg]	34.4							

Table 16: Parameters to produce the l	homogeneous	layer
---------------------------------------	-------------	-------

The compaction was uniformly performed for each layer with a manual proctor apparatus, assuming to achieve the 85% of the maximum wet density at the end of the compaction.

The test was performed with different equipment settings, varying plate diameter (150, 200 and 300 mm), weight (10, 15 and 20 kg) and drop height (13, 23 and 33 inches). Figure 20 shows the execution of the test and the different configurations of the device.

Figure 20: Assembling of the equipment in the configuration 300 mm diameter(a); Configuration 200 mm diameter and 15 kg mass (b); Configuration 150 mm diameter and 20 kg mass(c); Test execution (d)

For each settings configuration were performed eight measurements, the first four drops were applied to allow the material to exhibit only recoverable displacements. The last four measurements were recorded and used for the computation of the averaged values of the applied stress and dynamic modulus.

The non-linear behaviour of the granular material is clear when representing the relation between vertical stress and dynamic modulus (E_0) on a linear scale (Figure 21). The logarithmic trend shows a stress-strengthening behaviour characteristic of the granular materials, a similar behaviour was found testing the granular mixtures in the triaxial cell. It can be said that the dynamic modulus is sensitive to the applied stress and that the device is able to record this phenomenon.

Figure 21: Vertical stress - dynamic modulus (E₀) represented in a bi-log plan

4.2. On-site tests

In this stage, the sensitivity of the LWD to different levels of compaction was tested, plate load tests and sand-cone density measurements were performed, and in the end, the results of these tests were compared.

The on-site operations were performed in the Cavit plant in La Loggia (TO), where a multi-layer granular material system was prepared for the execution of the tests. The multi-layer system consisted of a natural subgrade, a 40 cm-thick unbound CDW (layer 1), and a 30 cm thick layer of the same CDW mixture (layer 2) (Figure 22). The area occupied by the preliminary field trial is a rectangle 10 m wide and 45 m long.

Figure 22: Multi-layer configuration

The schedule of the tests to be conducted included (i) one material sampling for each layer; (ii) LWD tests on four points of the subgrade layer, four points of the layer 1 and six points on the top layer; (iii) three plate load tests and three sand-cone density measurements on the top layer.

The operations were organised in a two-day program where for each layer were performed a sequence of tasks which included excavation procedures (for the subgrade) or material laying (for layers 1 and 2), layer compaction, and test execution. The field operations were organised as follows:

Day one: operations on subgrade and layer 1

- Subgrade:

At first, the 10 m x 45 m area was excavated to a depth of 70 cm, to this purpose an excavator, a dozer and two trucks were employed. Then the subgrade surface was compacted with 4 passes of a 200 tons dynamic roller (Figure 23).

Figure 23: Excavation procedure with excavator (a) and dozer (b); Compaction of the subgrade with a 200 tons dynamic roller (c).

During these operations, a sample of the natural soil was taken and sealed in an impermeable container, in order to determine the water content of the subgrade. After the compaction, LWD measurements were performed on 4 points located as described in Figure 24.

Figure 24: Tested points location

At each point, the LDW measurements were performed with a plate diameter of 300 mm, combining six apparatus settings, in particular, three drop heights (13, 23 and 33 in) and two masses (10 and 15 kg) (Errore. L'origine riferimento non è stata trovata.).

(a) (b) Figure 25: LWD device with three geophones (a); Test execution on the subgrade (b).

Although not necessary for the thesis objectives, all the field measurements conducted with LWD were performed with the three geophones configuration. In this way, further computations regarding back-calculated moduli could be done.

- Layer 1:

On the second part of day one, the first CDW layer was prepared and tested. The recycled aggregates were laid and compacted on top of the subgrade to obtain the 40 cm-thick layer. The compaction was performed with the same roller and number of passes used for the subgrade. After the layer placement operations were terminated, a sample of CDW was taken and sealed in an impermeable container, in order to determine the water content of layer 1. Then, the LWD measurements were performed at the location of points 1, 2, 3 and 4 as described in Figure 24, with the same device configurations adopted for the subgrade (plate diameter 300 mm, drop heights 13,23 and 33 in, and 10 and 15 kg mass). Figure 26 shows the execution of the operations on layer 1.

(a) (b) Figure 26: Placement of layer 1 (a); Test execution on layer 1(b).

Day 2: operations on layer 2

The second day was dedicated to the operations on layer 2. The layer is 30 cm thick and was divided into three 15 m-long sections with different compaction levels. The laying and compaction procedures were executed with the same procedures adopted for layer 1, except for the number of roller passes that was different for each section. Also for layer 2, a sampling of the material was performed to determine the water content. At the centre of each section were performed one plate load test and one sand-cone density measurement, while the location of the six points where the LWD tests were performed are shown in Figure 27. The same picture shows also the configuration of the sections with different levels of compaction. Sections 1, 2 and 3 were compacted with 4, 8 and 12 passes respectively. The location of points 1 to 4 are the same as the ones tested on the subgrade and layer 1, while points 5 and 6 are defined only for this layer.

The LWD measurements on layer 2 were performed in 18 configurations: plate diameters 150 and 300 mm; drop heights 13, 23 and 33 in; 10, 15, 20 kg mass).

Figure 27: Compaction level configuration and location of the points tested with LWD

In Figure 28 are shown the execution of the sand cone density and plate load tests.

(f)

4.2.1. On-site tests: results and discussion

LWD tests:

The LWD device was tested in different configurations to verify the sensitivity of the surface modulus to the applied vertical stress, in Figure 29 is reported, as an example, the vertical stress - surface modulus diagram obtained testing point 5 on layer 2.

Figure 29: LWD test result of point 5 on layer 2.

The measurements were performed with different device settings, the results were represented divided by plate diameter and mass. The non-linear (stress-hardening) behaviour of the granular material is visible from this diagram, the device was able to detect different modulus in different input configurations also in a real scale multi-layer system.

At each point, the measurements were performed with different device settings as summarised in Table 18.

Layer	Plate diameters	Masses	Drop heights	Points
Subgrade and layer	150 mm	10 and 15 kg	13, 23, 33 in	1, 2, 3 and 4
Layer 2	150 and 300 mm	10, 15 and 20 kg	13, 23, 33 in	1, 2, 3, 4, 5 and 6

Table 18: Device test configurations.

In the next paragraphs are shown the comparison of the LWD results between the tested points for each layer. The results are presented in hystograms, where the surface modulus E_0 is evaluated in the configuration with plate diameter 300 mm and 10 kg mass, the value represented in the graphs is the average modulus obtained obtained from all the drop heights (13, 23 and 33 in).

The LWD test on the subgrade showed that despite the same compaction level was adopted along the layer, the dynamic modulus at different points presented huge variations (Figure 30).

E₀ at different points of the Subgrade

Figure 30: Comparison of E_0 on the subgrade, evaluated with configuration plate diameter = 300 mm and mass = 10 kg (average value of all the drop heights).

According to these results, the modulus of the natural subgrade is three times higher on points 1 and 2, with respect to points 3 and 4. This suggests a higher bearing capacity of the first portion of the field trial (approximately from 0 up to 15 m, according to the reference system of Figure 24) with respect to the remaining part.

In Figure 31 are reported the results on layer 1. Comparing the results on the subgrade with the ones obtained on the same locations of layer 1, it's possible to see that the modulus didn't vary for point 1, decreased by 40% for point 2, while it increased by four and two times for points 3 and 4 respectively.

90 Eo Std. Dev 80 [MPa] [MPa] 70 59.33 Point 1 2.04 60 $[^{\mathrm{B}}_{\mathrm{B}}]_{\mathrm{H}}^{\mathrm{O}}$ Point 2 34.92 0.92 Point 3 74.08 3.32 30 Point 4 45.17 1.55 20 10 0 Point 1 Point 2 Point 3 Point 4

 E_0 at different points of Layer 1

Figure 31: Comparison of E_0 on layer 1, evaluated with configuration plate diameter = 300 mm and mass = 10 kg (average value of all the drop heights).

Layer 2 was divided into three sections with different levels of compaction, points 1 and 2 are located in the lower compacted section, points 3 and 5 in the middle section, while points 4 and 6 are in the high compacted section (Figure 27). Figure 32 shows the LWD results on layer 2.

 E_0 at different points of Layer 2

Figure 32: Comparison of E_0 on layer 2, evaluated with configuration plate diameter = 300 mm and mass = 10 kg (average value of all the drop heights).

On layer 2, the modulus ranged between 50 and 70 MPa in the first two sections and on point 6. Point 4 reported the highest value (around 130 MPa).

Sand-cone density and moisture content:

The samples of material of each layer were dried to obtain the water content, the results obtained in the lab showed a moisture content of 15.5%, 7.0% and 7.2% for the subgrade, layer 1 and layer 2 respectively. These outcomes show that the CDW material used during day one and day two had a uniform moisture content.

The sand-cone density results are reported in Table 19.

Section	W	$\gamma_{ m w}$	$\gamma_{ m d}$	γ d Situ $/\gamma$ d Max
	[%]	[kg/m ³]	[kg/m ³]	
1	6.2	2116.7	1994.0	95.4%
2	5.6	2196.5	2079.1	99.5%
3	4.9	2197.6	2094.3	100.2%

Table 19: Sand cone density results

The $\gamma_{d \text{ Max}}$ refers to the density of the "CDW and water" mixture obtained in the Proctor curve study, corresponding to a 7.2 % of moisture content (same moisture content obtained of the sample of layer 2). As expected, higher values of density were found in the sections with a higher level of compaction.

Plate load test:

The plate load test showed an increasing modulus passing from the low-compacted section to the high-compacted one (Figure 33).

The deformation modulus was found to be lower in the third section (although the more compacted one), this results could be affected by the lower bearing capacity of the subgrade below the highly compacted sections of layer 2, the dynamic modulus found in section 3 was three times

lower than the one in the first section. It is possible to notice the different levels of compaction of the sections considering the ratio Md/M'd, it increases as we move from a low compacted section to a high compacted one.

In the development of the INTREC project, a field trial to investigate the mechanical properties of the mixtures in real-scale conditions will be developed. The experimental site will be located in the Cavit plant, and it will consist of a roadway 8 m wide and 320 m long. This chapter describes the design of the road, the planning and scheduling of the tests that will be performed and the computation of the amount of material necessary for the construction of the field trial.

5.1. Materials

Based on the results of the laboratory investigation (paragraph 3), seven mixtures were selected to be tested in the field trial. In particular, three mixtures composed of recycled aggregates stabilized with non-traditional binders, two mixtures stabilized with CEM II, and two unstabilized mixtures were selected.

The first mixture to be selected was CDW + AS2, among the alkali-activated stabilised mixtures, reported the highest RM and UCS at 7 days of curing, also the ITS was found to be one of the highest values. Moreover, unlike AS1, AS2 has the advantage to be a ready-made solution produced in the plant. The mixture stabilised with "Hybrid" cement reported lower mechanical properties with respect to the one containing CEM IV/B, which reported higher values of UCS and ITS of about 60 and 27% respectively. CDW + 3 CEM IV/B reported the highest stiffness at 7 days among all the mixtures stabilised with non-traditional binders. The cement type IV is obtained by mixing 50 % of cement type II with 50 % of calcinated clay, providing remarkable advantages from the sustainability point of view, it represents a good compromise between the less performing "hybrid" cement and the traditional CEM II. Regarding the mixtures stabilised with Bondafix, the best compromise between mechanical properties and amount of binder was found to be in the CDW + 8BF.

Table 20 reports the composition of mixtures.

Mixture/section n°	Aggregates	Binder	Water	Mixture name
1	CDW	CDW fines + AS2	-	CDW + AS2
2	CDW	CEM IV/B	8.5%	CDW + 3 CEM IV/B
3	CDW	Bondafix	8.5%	CDW + 8BF
4	CDW	CEM II	8.5%	CDW + 3 CEM II/B
5	NAT	CEM II	6%	NAT + 3 CEM II/B
6	NAT	-	6%	NAT and water
7	CDW	-	8.5%	CDW and water

Table 20: Mixtures for experimental site

The mixtures stabilized with CEM II ($n^{\circ} 4$ and $n^{\circ} 5$) will be used as a reference to compare the performance of the mixtures stabilized with non-traditional binders ($n^{\circ} 1$, $n^{\circ} 2$ and $n^{\circ} 3$). The unstabilized granular mixtures ($n^{\circ} 6$ and $n^{\circ} 7$) will provide a reference to compare the differences between stabilised and unstabilised blends. To each of these mixtures, a section of the subbase layer of the field trial roadway will be dedicated.

The 320 m-long roadway will be subdivided into 7 sections as reported in Errore. L'origine riferimento non è stata trovata.

Figure 34: Field trial layout

The first 108 m will be divided into three sections of 36 m each and will be dedicated to the mixtures stabilized with non-traditional binders. Sections 4 and 5 are also 36 meters long and will house the two mixtures stabilized with CEM II. The last two sections are dedicated to the study of the unbound mixtures and each of them will be 70 m long.

5.2. Operation schedule

The construction of the field trial and the monitoring tests are organised in a 19 days schedule.

Day 1: tests on subgrade

During the first day of field tests, three operators are employed to perform the tests and sampling operations on the subgrade layer.

Two operators will carry out four Plate load tests on the subgrade layer of the field trial at different locations. The tests shall be developed on the centreline of the alignment at the distances from the starting point of the road indicated in Table 21.

Table 21: Location along the centreline of the plate load tests

Test 1	Test 2	Test 3	Test 4
25 m	75 m	125 m	200 m

The methods of the test have been described in paragraph 2.4.2.

Another operator will be involved in the ten dynamic plate tests and in-situ density measurements on the subgrade layer. The tests are planned to be carried out on the centreline of the alignment, seven tests at a distance of 20 m from each other will be performed on the section dedicated to the bound materials and three tests at a distance of 30 m from each other will be performed on the section dedicated to the unstabilised materials. The distribution of the tests is described in Table 22.

Table 22: Location along the centreline of the dynamic plate load tests

Test 1	Test 2	Test 3	Test 4	Test 5	Test 6	Test 7	Test 8	Test 9	Test 10
10 m	30 m	50 m	70 m	90 m	110 m	130 m	180 m	210 m	240 m

The two in-situ density tests will be carried out at a distance of 70 m and 120 m from the beginning of the field trial, at a distance from the centreline, to avoid interference with the plate load tests that are being developed contemporarily. The methods of the tests are described in paragraph 2.4.

The sampling of the subgrade material is also planned to investigate the characteristics of the subgrade (i.e., the granular size distribution) at the laboratory. For this purpose, a total amount of 45 kg of subgrade soil will be sampled and stoked in three bags.

Day 2: sampling raw material

ITS: Indirect tensile strength

Before the starting of the construction phases, raw materials for the future preparation of specimens for laboratory testing has to be sampled. Two operators are required to perform these sampling operations. Table 23 reports the volume of raw materials to be collected for each mixture to prepare the specified number of cylindrical specimens.

	Sample type	Test	Quantity	Diameter	h	Volume
			[-]	[mm]	[mm]	[m ³]
ys						
7 da	Thin sample in plastic mould	RM+UCS	3	100	186	0.00438
ter `	Stubby sample in small metal mould	UCS	3	100	100	0.00236
Af	Stubby sample in large metal mould	ITS	3	150	120	0.00636
ter lays						
Afi 28 d	Thin sample in plastic mould	RM+UCS	3	100	186	0.00438
						_
	RM: Resilient modulus with triaxial cell			Total volume	0.01748	
	UCS: Unconfined compression strength			[m ³]		

Table 23: Samples to be produced for each mixture type

The sampling will be performed on the single components of the mixture, therefore it is necessary to compute the amount of each element separately (Table 24).

MIXTURE	γd	Wopt	Binder	M _{solid}	Maggregates	Mbinder	Mwater	M _{tot}
	[kg/m ³]	[%]	[%]	[kg]	[kg]	[kg]	[kg]	[kg]

я	* In the case	of AS2 the	e water cont	ent refers t	o the alkaline s	solution.		

Table 24: Mass content for each component of the mixture

In order to have a sufficient amount of material, a safety factor equal to 1.7 is applied; the final quantity of each material to be sampled is summarized in Table 25. The table reports also the bags and/or containers that are necessary to store the materials.

Material	Quantity [kg]	Bags
Aggregates CDW	350	24
Aggregates NAT	140	10
Alkaline solution	5	1 container
Bondafix	5	1
Cement IV-B	2	1
Cement II	4	1

Table 25: Materials quantities and necessary containers

In Table 26 is reported the GAANT dyagramm for the operations of days one and two.

Table 26: GAANT activities of days one and two

Day 3: laying the unbound mixtures and mixtures sampling

The two sections of the subbase layer composed of unbound material (NAT and water and CDW and water) will be placed and compacted in the position described in Figure 34. For the same mixtures, material sampling will be developed.

For this task, three operators are needed, one operator will be required to supervise the laying and compaction operations, and the other two will be employed in the sampling procedures.

The amount of material to be sampled is the same as the ones reported in Table 23. The quantity by mass is calculated in Table 24. Also for this operation, the amount has been increased

with a safety factor of 1.7, therefore, for each mixture has to be sampled 70 kg. After the sampling, the fresh mixture is moved to the Cavit laboratory where will be compacted and sampled following the manual Proctor procedure. The operations to be performed are:

- Sampling of 70 kg of material for each type of mixture: the operators take the material with a wheelbarrow, and make sure to cover the mixture to avoid evaporation of water;
- In the laboratory, the operators will prepare the samples that are reported in Table 23, with a manual Proctor compactor;
- The samples are sealed and placed in a humid environment to avoid moisture loss;
- The samples are moved to the Politecnico laboratory for the tests that will be developed the next day.

In the meantime that the sampling is being performed, the second operator will be following the operations in section 6 of the field trial, where, a 30 cm thick and 70 m long layer of unbound NAT aggregates will be laid. After the layer is compacted, a CDW unbound mixture layer, of the same thickness and length, can be placed and compacted in section 7. At the end of the operations, the following tests are developed:

- Thickness control: three checks for each mixture;
- In-place density: one test for each mixture, as reported in paragraph 2.4.3

Day 4: tests on unstabilised mixtures

The laboratory and in situ tests on the unbound mixtures are performed on the day after the layers have been laid. Five operators are employed for these tasks.

Two operators are needed to perform the laboratory tests in the Politecnico laboratories, for each mixture will be performed the UCS, ITS and RM tests reported in Table 23. The tests will be performed on the cylindrical samples as described in paragraphs 2.3.3, 2.3.4 and 2.3.5.

Three operators are required in the in-situ tests on the compacted layers (CDW and NAT unbound mixtures). The following tests and repetitions are planned to be carried out:

Plate load tests: 3 tests on the NAT layer and 3 tests on the CDW layer, a Cavit vehicle will be used as a counterweight;

Dynamic plate load (LWD): 10 tests on the NAT layer and 10 tests on the CDW layer.

In Table 27 is reported the GAANT dyagramm for the operations of days three and four.

Table 27: GAANT activities of days three and four

Day 7, 8 and 9: laying the stabilized mixtures and sampling:

In the timetable that was prepared, days 5 and 6 are supposed to be non-working days. During the following days (7, 8 and 9) will be placed the stabilised mixtures. On days 7 and 8 will be placed two mixtures per day, during day 9 it will be placed the last mixture, so to place five stabilised mixtures in total according to the scheme of Figure 34. The procedure for day 7 is described in the following paragraphs, the same procedure should be repeated on days 8 and 9.

One operator will be employed in section 1, where a 30 cm thick and 36 m long layer of the first mixture will be laid. Four additional meters of subbase will be laid in order to allow the roller to adequately compact the entire section. After the layer is compacted, the additional 4-meter segment is removed, and the adjacent subbase material can be placed and compacted with the same procedures. At the end of the operations, the following tests are developed:

- Thickness control: 3 checks for each mixture;
- In-place density: 1 test for each mixture, as reported in paragraph 2.4.3.

For both types of mixtures, the sampling operations will be performed by two operators following the same procedure as reported for the unstabilised mixtures on day 3.

In Table 28 is reported the GAANT dyagramm for the operations of day seven to day nine.

Day 10, 11 and 12: in situ tests on stabilised mixtures

The in situ tests will be developed after 3 days of curing, the following procedure refers to day 10, where will be tested the mixtures 1 and 2 (placed during day 7), the same procedure will be repeated for mixtures 3 and 4 on day 11, and mixture 5 on day 12.

Two operators are employed to perform 3 plate load tests on both sections 1 and 2. The tests will be executed on the centreline at a distance of about 10 m.

The remaining operator will perform 10 LWD tests on section 1, and 10 LWD tests on section 2. The measurements will be carried at a distance of 2.5 m from the centreline (left side and right side), with a longitudinal spacing of 3 m.

In Table 29 is reported the GAANT dyagramm for the operations of day ten to day twelve.

Day 14, 15 and 16: 7-days laboratory tests:

In the timetable that was prepared, day 13 is supposed to be a non-working day. During days 14, 15 and 16, will be performed the 7 days laboratory tests, in particular, on day 14 will be tested the mixtures 1, 2, on day 15 will be tested the mixtures 3 and 4, and on day 16 will be tested the mixture 5. It will be employed one operator to develop the UCS, ITS and RM tests reported in Table 23, the methods were described in paragraphs 2.3.3, 2.3.4 and 2.3.5.

In Table 30 is reported the GAANT dyagramm for the operations of day fourteen to day sixteen.

5.3. Quantities estimation

The quantity of material needed for the construction of the field trial was estimated considering the cross-section of the road, and a safety margin of 10%. The road that needs to be built is 320 m in length and 8 m in width. The pavement layer thicknesses were designed according to a specific structural model: a fixed thickness (30 cm) of the subbase layer was maintained, while the design life of the top hot mix asphalt (HMA) layer was estimated depending on the subbase material. The design of the pavement was based on estimates of the traffic levels of heavy vehicles travelling from and to the Cavit plant. The results of pavement design in terms of design life of HMA for different subbase materials are reported in Figure 35. For sake of clarity, the structural calculations were not part of this thesis but were considered as input parameters for quantities' estimation.

Figure 35: Pavement expected life given a 30 cm thick subbase as a function of the HMA layer thickness.

According to the results of the structural design of different pavement solutions, the HMA layer thickness was chosen to be 12 cm to balance economic requests of Cavit S.p.a and structural requirements. In conclusion, the selected pavement cross-section is composed of a compacted subgrade, a 30 cm-thick subbase and a 12 cm-thick HMA, Figure 36 shows the pavement cross-section.

Figure 36: Pavement cross-section

The quantity of material needed for the construction of the field trial is reported in Table 32.

6. CONCLUSIONS

Civil works represent one of the main sources of waste materials. In Italy, the waste generated by construction and demolition activities is increasing. In 2019, it represented the 45.5% of the total special wastes produced (ISPRA, 2021). Recycling processes allow reusing part of this material and, in particular, the use of aggregates from construction and demolition waste (CDW) has aroused interest in the road sector. The advantages of using CDW recycled aggregates in substitution of virgin ones include the reduction of material destined to landfill, the preservation of natural resources, and the overall reduction of costs. In this context, CDW represents an opportunity for the sustainable development of pavement constructions. The use of aggregates deriving from waste material processing (CDW) has been intensifying in those construction applications that do not require high mechanical performance. An improvement in the mechanical characteristics of CDW mixtures can be achieved through stabilisation. This practice is still not common and, when implemented, it involves traditional Portland cement whose manufacture processes are expensive and generate large amounts of CO₂. For this reason, the advantages of using CDW aggregates can be compromised by the use of traditional binders. Therefore, the use of binders with reduced environmental impact is mandatory. In this framework, the INTREC project aims at developing new solutions for the formation of subbase layer of road pavements. The thesis carried out is part of INTREC, and its objective is to partly cover the gap in scientific knowledge on the properties of CDW mixtures stabilised with innovative binders.

For these purposes, different mixtures for the formation of subbase layers of roads were analyzed and compared. In particular, materials obtained both through the use of natural virgin aggregates and recycled aggregates have been considered. The aggregates have been combined with ordinary and non-traditional binders. The study was divided into two stages, the first was dedicated to the laboratory study aimed at the characterization of the mechanical properties of the mixtures, while the second one concerned the design of a field trial to test the real-scale behaviour of the materials.

The laboratory study started with the determination of the OMC and MDD of the mixtures through the Proctor study, this step allowed the production of samples by means of the gyratory shear compactor. Then, the mechanical properties such as workability, resilient modulus, UCS and ITS were tested. The results showed that the blends stabilised with Bondafix exhibited increasingly performance in strength (UCS and ITS) as the binder content increased. In terms of stiffness, the binder dosage did not affect remarkably the results. Conversely, the curing time was found to be the main cause affecting the reduction of RM, evaluated at I_1 = 275 kPa, the resilient modulus of CDW + 8BF decreased by 26% when passing from 7 to 28 days of curing time. The reduction of stiffness in the long-time cured samples has been found to be common in most of the mixtures types, this may be due to the increase in moisture contents of the samples that occurs in the humid environment.

Regarding the mixtures containing CEM IV/B, results from Avellino and Gugliotta (2021) on the mixture CDW + 3CEMIV/B and the one tested in this study, CDW + 3IB, were compared. CDW + 3CEM IV/B exhibited superior properties compared to CDW + 3IB; this can be due to the different amounts of calcinated clay present in the blends, 50 and 75% respectively. The first blend presented a UCS of about 1.7 MPa both at 7 and 28 days, while the second one reported 1.1 and 1.4 MPa at 7 and 28 days respectively. The CIRS threshold was reached only from the first blend with 0.27 MPa. Regarding the resilient modulus, the blend stabilised with CEM IV/B reported the highest value among all the tested mixtures, 638 MPa at 7 days (I₁=275 kPa). Conversely, after 7 days of curing the mixture stabilised with "hybrid" cement showed a stiffness in line with the other mixtures, but a reduction of 44% when passing to 28 days.

The last mixtures to be tested were the ones stabilised with alkali-activated CDW fines, all of these mixtures satisfied the CIRS threshold, and the blends containing AS1 and AS2 showed an ITS above 0.34 MPa. Concerning the compressive strength, at 7 days, CDW + AS2 reported a UCS similar to the reference mixture NAT + CEMII/B (1.84 and 1.86 MPa respectively). The RM of CDW + AS3 was the only one to report an increase with the curing time (30% evaluated at I₁=275 kPa), while the blend stabilised with AS2 reported the highest values of the M-EPDG parameters k1 and k2 at 7 days (3868 and 0.54 respectively).

After the laboratory tests, seven mixtures were selected to be tested on a real scale, the criteria that were adopted concerned both the evaluation of the mechanical performance and the environmental sustainability of the choice. The blend containing AS2 was selected taking into consideration the fact that it is a ready-made solution produced in the industrial plant. Regarding the CEM IV/B, despite the sustainability advantages brought by the use of the mixture CDW + 3IB, the mechanical properties turned out to be not as suitable as the ones exhibited by the blend containing "pure" cement type 4. Therefore, between these two, the choice fell on this last mixture. The Bondafix binder showed promising results and the mixtures containing it presented

an increasing performance trend together with the binder content. However, considering the impact on environmental sustainability, the choice fell on the 8% of binder content. In the end, the mixtures NAT + 3CEMII, CDW + CEM II, the unbound mixtures containing natural and recycled aggregates were selected to provide a comparison between the behaviour of the traditional materials and the studied mixtures.

Preliminary site operations were carried out in order to test the sensibility of the LWD to the different input configurations and to the different levels of compaction of the material. These activities were developed both through a laboratory simulation and through a site test on a multilayer system. The laboratory simulation was performed on an unbound CDW layer built in a PVC box where LWD tests were developed with different device settings, the equipment recorded a non-linear stress dependence of the LWD modulus, in particular, a stress-hardening behaviour. The LWD sensitivity to different input parameters was tested on a real scale multi-layer system. The sensitivity of the device to the different levels of compaction was more difficult to be appreciated considering the great number of variables affecting the multi-layer system.

After the preliminary activities, the design of the experimental site was carried out. At first, the location of the experimental road was defined in accordance with Cavit company. Then, the schedule and the operations to be performed were defined considering the configuration of the site and the available equipment. The operations were organised avoiding the conflict of different tasks, accounting for the time needed to perform the tests, and including the necessity of testing the mixtures after a correct curing time. The planned operations included subgrade characterization and material sampling, laying and compaction supervision, static and dynamic load tests, density measurements and laboratory tests.

Since the road cross-section was defined through a structural model, the subbase and the HMA layer thickness were used for the estimation of the material quantities, these computations accounted for a safety factor.

The schedule of the experimental field trial ends with the 28-days tests of the mixtures, this allows the mechanical characterisation of the materials. However, the continuous monitoring of the pavement in time will be fundamental in order to determine the real scale behaviour of the different solutions. Only in this way, it will be possible to assess the reliability of these CDW mixtures subbase layers. To this end, the choice of the location of the experimental site was fundamental. In fact, as the road leads to the Cavit plant, will be travelled by heavy vehicles. Moreover, the traffic at which the road is subjected could precisely be determined since almost all of the heavy vehicles passing will be documented in the company records.

Acknowledgements

I would like to offer my special thanks to Professor Marco Bassani and Assistant Professor Luca Tefa, who supervised the research activities and supported me in the development of the thesis. I am particularly grateful for the knowledge that they were able to transfer to me during these challenging months. I would like to extend my thanks to the Cavit S.p.a company for allowing me to be part of this important research project.

Ringraziamenti

Voglio in fine ringraziare la mia famiglia e gli amici che mi hanno supportato durante questi anni impegnativi, senza il loro sostegno non sarebbe stato possibile raggiungere questo traguardo. Un grazie particolare va alla mia compagna Vanessa, che con grande pazienza mi ha accompagnato in tutto il percorso di studi e con cui ho potuto condividere le difficoltà incontrate.

#### 8.5.2. LWD test on multi-layer

For each point are represented two tables, the first table represents the raw data (8 drops), and the second represents the average values plotted in the diagram, the average values are computed from the last four drops out of a total of eight.

# Subgrade:
