#### Abstract

Preserving historical cultural property, transferring historical buildings to future generations, and preserving architectural features that have been abandoned for centuries due to natural disasters, fires, wars, and apathy toward adverse environmental conditions are all important values that are currently the subject of many science and art branches.

There is a dearth of an effective and long-term knowledge of how to conserve historical structures. The fact that structural evaluation and conservation procedures are a complicated topic with numerous challenges and ambiguities is one of the most fundamental reasons for this. This necessitates a collaborative approach to work. A full static and dynamic examination of these structures in conformity with contemporary standards is necessary in order to reuse them and make them endure longer.

The C Hall of the Turin Exhibition Center, a prominent 20th-century structure, was meticulously inspected and the structural evaluation done in this research, with the goal of identifying problems, proposing solution suggestions, and emphasizing a sustainable and effective conservation method.

Pier Luigi Nervi, one of the most recognized architects and engineers of the period, constructed the Turin exposition hall, which became an iconic edifice in the years following World War II. Hall B was constructed initially, followed by Hall C two years later. This construction, made of reinforced concrete and prefabricated parts, is credited as being the first to test Nervi's innovation, ferrocement.

In this study, critical elements were determined by seismic evaluation of the structure using a low-fidelity beam model, after which historical information about the building was discussed, Nervi's Construction methods were emphasized, and finally, critical elements were determined by seismic evaluation of the structure using a low-fidelity beam model. Then 11 critical elements have been chosen from the structure. These elements have all been verified using a combination of static and dynamic loading. These combinations have been examined by a shear assessment and a normal-moment interaction diagram. As a result, it was attempted to validate these aspects using existing standards. As a consequence, solution approaches based on the structure's response to a seismic influence on the structure were attempted to be offered.

## Chapter 1

## 1. Introduction

Due to the numerous uncertainties, determining and analyzing the behavior of a historical and monumental structure is a very difficult task. Therefore, such investigations are so significant from a technical and scientific standpoint, as they strive to conserve the building's architecture and track it over time.

When it comes to Italy's historical structures, we can state that its historical and cultural heritage is vast, and this topic is always current. When we consider the last few years, the importance of such reinforced concrete structures has gradually increased due to changing and increasing technology and research, necessitating the need to update prior norms. Today, it is possible to say that relatively little effort has been done to restore reinforced concrete structures, the most widely used building material on the all over world.

As a result, proposals for various experiments and redesigns for the preservation of such structures began to be developed. It is the goal of this project to determine the important components of such structures as well as the factors that affect them by partnering with significant institutions throughout the world.

The goal of this thesis is to do a seismic assessment of Pier Luigi Nervi's exhibition hall in Turin, Italy. To do so, you'll need to know the building's materials, geometric structure, the environment it's in, the standards in place at the time it was created, and the current construction structure and earthquake requirements.

Considering the movements generated by the earthquake is one of the most significant aspects of the architecture to consider. In cities with a high seismic risk, such as Turin, it's critical to take into account the earthquake effect. The goal of this research is to calculate and verify the critical modes of crucial elements and to evaluate the seismic motions to be made by examining the response spectra.

The most essential elements and the most stressed elements were analyzed in the findings obtained by applying the earthquake in the $x-y-z$ direction. A low fidelity model was used in the analytical process. The behavior of only one-dimensional (BEAM188) elements is used to create this phrase.

As stated at the outset, the examination and correct analysis of the reinforced concrete and prefabricated reinforced concrete elements, which have a very complex and important future for this structure, will aid in the development of an appropriate response method and plan for the protection of architectural works with insufficient references and guidelines.

## Chapter 2

## 2. Case of Study: Turin Exhibition Center

Some politicians and businesspeople in Turin want to build a contemporary exhibition hall to help the city fast recover from the devastation caused by WWII. Thus, in 1948, the Turin exposition hall was constructed on the site of the auto show in the Valentino Park, which had been largely wrecked by the war. [1]

Figure 2.1 Exterior of the complex of Torino Esposizioni in 1960 (Archivio Storico Fiat, Torino), [17]
An innovative structure, designed by Nervi and Bartolli and made of reinforced concrete and prefabricated parts, has emerged as the world's first structure to utilize Nervi's innovation, ferrocement. [1] Pier Luigi Nervi, an engineer and architect, created a precast construction for the enormous center hall. The hall has a roughly square plan with two side galleries, labelled B and C, and a semicircular apse, covering an area of approximately 200 square meters. Heavy structures are located beneath it in a semicircular hall. He used a reinforced concrete he devised called ferrocement on the sloping roof of the Turin exhibition hall he constructed (iron cement). Spraying cement mortar over a mesh of tiny steel wires to build layers of desired shape and thickness resulted in light and durable shell pieces. The great hall's ferrocement roof spans 96 m x 75 m and is connected to each other. The length and thickness of these wavy roof components are 4.40 m and 4 cm , respectively. On average, the vault is less than 8 cm thick. The ability to close large-width spans with little material is crucial for this structure, and the lightweight material decreases construction time.

Figure 2.2 Scaffolding for the construction with prefabricated elements [2]
Price, time, and the atmosphere produced by war were some of the most difficult difficulties for P.L. Nervi to design. Nervi has chosen a prefabricated element technique as the best answer to these issues. The construction of the building began in 1948 with the most important hall, Hall B or Hall Agnelli.

Figure 2.3 Interior of the Hall B in 1948

Nervi has employed structurally efficient and cost-effective approaches, such as thin, light shells that maintain the architectural rhythm. Nervi used prefabrication and ferrocement materials defined by the client to overcome the time, cost, and other challenges indicated in the contract in order to obtain the required outcome. Rather than being original, Nervi's techniques arose from a desire to find answers to the aforementioned challenges. [3]

Figure 2.4 the Hall C during its construction site in images of the time in 1950, the assembly of the diamond elements in ferrocement on the vault centering. (Archivio MAXXI Roma, Fondo Nervi.)

A contemporaneous hall, Hall C, was erected two years after Hall B, or Salone Agnelli, was completed. The size of Hall C is less than that of Hall B. The prefabricated materials and design ideas employed in the building of Hall B were also utilized in the construction of Hall C, resulting in a perfect blend of components. He set out to solve the most challenging structural challenge by determining the best technique and building system for passing large spans in a cold environment in a short amount of time. For one and two curvature roofs, he used ferrocement as prefabricated pieces and material. As a result, it was able to cross huge spans without the use of particularly demanding parts or materials due to the so-called resistance to form. [3]

Figure 2.5 Plan of Torino exhibition center

This structure, with its effective architectural and unique material, may be merged with the benefits of the construction process. One of the most crucial transition pieces is the one that connects the corrugated roof to the structural piers. A prefabricated framework of rhombic components linked by reinforced concrete ribs was used to construct the Rotunda's 40 -meterdiameter semi-dome. The structure is completed with a ferrocement plate for top-wheeled vehicles. The ribs have a 7 -millimeter depth of detail.

The inside ribs serve as a functional and beautiful architectural feature. The lower-level ceiling slabs and side galleries of the hall have been replaced with 7.50 m long precast beams with a double curve and support, which are linked and structurally supported by a thin floor slab.

### 2.1 Salone Agnelli Or Hall B

Figure 2.6 Interior of Hall B

It gradually diminishes towards the supports until the structural hypothesis of a two-hinged arch is satisfied, which is congruent with the calculation approach utilized, and the undulations are largest at the ridge level. As a result, just two-thirds of the vault's arch is divided into spans. In Hall B, you can examine the architectural and structural design that he used in his prior works. The slanting form of the columns supports the gallery by providing perfect shelving on the long side of the space and a horizontal ceiling facing the horizontal loft on the first level.

The most statically interesting part of pavilion B is the apsidal section, which summarizes Pier Luigi Nervi's undeniable talent; it provides a highly harmonious, aesthetically valid, and welllit structure in which the semi-dome discharges its horizontal response into a hardened annular floor that functions like an arch placed on a horizontal plane.

The structure's primary elements are depicted in the diagram below.

Figure 2.7 structural concept of Hall B
When we consider the facts already provided, we can see that Hall B is a complicated structure. The structure is made up of a variety of various parts. It's made up of 390 prefabricated parts in seven depths, as well as slanted columns and fan elements created by Nervi for low loads.

### 2.2 Hall C

The decision to expand the Turin Exhibition Hall was made in 1949, and hall C was constructed. Nervi was in charge of the design. Nervi is having difficulty dealing with a few issues. After a few attempts, he was able to solve them. First and foremost, there was a deadline for the hall, which would be $65 \times 50$ meters in size. He erected a vaulted ceiling with a 10 m long perimetric plate after numerous attempts. As a result, materials including prefabricated parts and ferrocement, which were employed for Hall B's half dome, began to be utilised.

Figure 2.8 Hall C plan and section (from the Rassegna tecnica della Società degli ingegneri e architetti in Torino)
He employed an undulating reinforced concrete beam structure, something Nervi had considered but never tried before. As a result, the environmental problem has been solved. Nervi got the patent for this system (patent number 465636) on May 19, 1950, in Rome, once it was completed. [4]

It developed its patent number 445781, which was registered on August 26, 1948, after the building of the Turin exposition hall was finished. These patents became a distinguishing aspect of Nervi's style, and it was widely adopted in the years that followed. [5] [4]

Figure 2.9 construction of the roof
On four arches, he built the magnificent vault of the hall. These arches were angled in accordance with the vault's thrust and the weight of the surrounding roof fog. The reinforced roof system's horizontal stiffness was meant to disperse and balance the vault's thrust. "The vault is computed as a thin membrane vault as well as a vault made up of elemental arches, each of which is resistive on its own," Nervi says.

Figure 2.10 Interior of Hall C today

## Chapter 3

## 3. Modelling

Important qualitative and quantitative information gathered via a very rigorous and in-depth review of calculation reports and execution project tables is utilized to recreate the Turin Exhibition Hall as accurately as possible. The geometry of the building must be created before mechanical modeling can begin. Thus, by making modeling decisions, we will be able to achieve our desired aim to a large extent. In this situation, a low-quality model was constructed that was appropriate for our global analysis and will be calibrated for future uses.

### 3.1 Finite Element Method

The finite element method (FEM), also known as finite element analysis (FEA), is a computer methodology used in engineering to generate approximate solutions to boundary value issues. The Finite Element Method is an analytical method in structural engineering that allows for 3dimensional static and dynamic analysis of structures, linear and non-linear solutions, and results that may be shown numerically or visually. [6]

The finite element method is a popular approach for estimating the behavior of structures under static and dynamic loads, as well as determining structural element stress. This strategy, which is preferable in terms of speed and cost, allows you to combine numerous construction element models (rod, shell, plate, prism (solid)). [7]

Figure 3.1 FEM - Basic Concepts: a) A General Variable P(x,y) b) Triangular Finite Element c) Triangular [6]
With reference to Figure 4.1, the general concepts and terminology of finite element analysis will be explained. The illustration represents a volume of a substance or materials with known physical qualities. The domain of a boundary value issue to be addressed is represented by the volume. For the sake of simplicity, we will consider a two-dimensional situation with a single field variable ( $\mathrm{x}, \mathrm{y}$ ) to be determined at each position $\mathrm{P}(\mathrm{x}, \mathrm{y})$ so that a known governing equation (or equations) is fulfilled exactly at each such location. [6]

A mathematical solution, that is, a closed-form algebraic expression of the independent variables, is achieved. In practice, the domain, as well as the governing equation, may be geometrically complicated, and the possibility of achieving an accurate closed-form solution is quite low. As a result, in engineering assessments of complicated issues, approximate solutions based on numerical approaches and digital computing are most frequently achieved. Finite element analysis is an effective tool for getting accurate approximation solutions. [6]

The information collected from the experimental data was utilized to model the elements in order to get their mechanical behavior. All structural aspects of the geometric model were employed exclusively in ANSYS for this by using Beam 188 element types.

Figure 3.2 AutoCAD 3D model perspective view

Figure 3.4 AutoCAD 3D model front view

## Mechanical parametric design software

APDL is a programming language in its purest form. Because the commands in the ANSYS application may be defined in a parametric language, users can conduct repeated processes automatically. To put it another way, setting values to variables ensures that these values may be used throughout the study. The results of calculations on parameters set using various expressions and functions may be shown to the user. The user can be notified at intermediate stages and requested feedback by using loops and logic inquiries. Additionally, by constructing macros from scripts, a whole analysis may be performed automatically.

ANSYS software was used to construct a mechanical model. The core geometric model, which was originally produced in AUTOCAD 3D, was imported to ANSYS MECHANICAL APDL. After that, the element type in the imported geometric model was determined. (See BEAM 188 for further information.) The building's material kinds were then defined. The building's materials were created using characteristics including elastic modulus, Poisson's ratio, and density. Because these qualities in the construction materials have an impact on the mass and stiffness of the structure, they should be carefully analyzed as a key parameter. The beam components' cross-sections were specified as rectangular, and then the structure's materials, element type, and cross-sections were assigned to the necessary elements. The entire structure was then meshed. The building's boundary conditions were then determined. As a result, the model was developed in order to do the analysis we desired.

Figure 3.5 Ansys exporting model from AutoCAD $3 D$

Figure 3.6 ANSYS model top view

Figure 3.7 ANSYS model front view

As previously stated, the structure was constructed entirely of beam type pieces, resulting in a model that was both versatile and adaptable. However, defining some elements that were not accurately represented by beam elements proved problematic. In these circumstances, truss structures with beam components are built using an imagined material specified as having the same stiffness and mass as the real structure.

## Beam 188 Element type

We must assign and specify degrees of freedom to the nodes in order to construct a mechanical model. To assign this parameter in the Ansys Mechanical APDL Software, you must first describe the kind of element to be utilized. Only BEAM188 components were utilised in this example. The attributes of the Beam188 element type, as described in the program, can be found below.

Figure 3.8 Beam 188 element type properties
A basic step in the finite element analysis approach is to discretize the geometric elements by creating a mesh. This approach is not especially onerous in the example in question, with just one-dimensional parts and a need to study the general behavior of the structure. In reality, the finite element's unit length is specified.

This element, which pertains to the Timoshenko beam theory, is often employed for slender or somewhat thick beams. The continuous shear strain throughout the cross section is then taken into account. The application cannot be extended to components that are too stocky for the first order theory utilized to evaluate shear deformability. In reality, using Timoshenko's theory results in the conservation of plane sections after deformation, which could not possibly be the ideal representation for an element that differs too much from a beam. The ratio of shear stiffness to bending stiffness (GAL2 / EI) may be used to determine the element's applicability, and a value of more than 30 is preferred.

To make model in Ansys Mechanical APDL, it has been used 11232 elements, 7141 line has been created and 27 different material model has been defined.

## Chapter 4

## 4. Eigen-Value Analysis

Eigen-value analysis is a technique for determining the structure's free vibration periods and mode forms. The mass and stiffness matrices of the structural system may be used to derive free vibration periods and modes.

The account comes with 100 modifications. In general, even though these modes appear to be in big numbers, mass participation rates reveal that much more may be acquired. The mass participation ratio expresses how much of the overall mass of the structure may be activated and involved in the oscillating motion by a mode vibration corresponding to a free vibration period.

There are two methods for doing modal analysis of structures: theoretical and experimental. The mass, damping, and stiffness attributes of the structure are used to create a physical description in theoretical modal analysis. The analytical model of the structure is created using these physical features. The standard modal analysis approach using the analytical model is used to get the structure's natural frequencies, mode shapes, and modal damping ratios. The modal model of the structure is generated using these data. The values obtained are known as natural values since no external load is applied to the structure during the modal analysis. Finally, the modal model is used to determine the structure's response under the provided boundary conditions and loadings. These reactions, known as frequency and push behavior, are used to develop the structure's behavior model.

The force (i.e., effect) applied to the structure and the acceleration (i.e., reaction) produced from the structure are measured and analyzed in experimental modal analysis of structures. The frequency response function, which will be used to determine the dynamic properties of the structure, is produced from the ratio of the response to the effect after the effect and response values have been measured.

In order to define dynamic analysis of structures, modal analysis is used. To acquire a sufficient number of vibration modes, it used Eurocode 8: Design of buildings for earthquake resistance. According to Eurocode 8, the total effective mass participation factor for vibration modes operating on a structure must be larger than $90 \%$ in each direction. As a result, the vibration modes with the highest effective participation factor are considered, and they must be used until 90 percent of the total is reached. The vibration modes having a participating mass larger than or equal to $5 \%$ of the total mass under investigation were chosen using the reference criteria in paragraph 7.3.3.1 of NTC 2018.

### 4.1 Mass Participation Factor

| MODE | FREQUENCY ( Hz) | PERIOD (s) |  | MASS X <br> $(\%)$ | MASS Y <br> $(\%)$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{1}$ | 2.45618 | 0,40714 | 18.26 | 15.83 | MASS Z <br> $(\%)$ |
| $\mathbf{2}$ | 2.53911 | 0,39384 | 0 | 0 | 5.62 |
| $\mathbf{3}$ | 3.36930 | 0,29680 | 0 | 37.12 | 0 |
| $\mathbf{7}$ | 4.00873 | 0.24946 | 7.46 | 0 | 0 |
| $\mathbf{8}$ | 4.42008 | 0.22624 | 11.33 | 0 | 0 |
| $\mathbf{9}$ | 4.70036 | 0.21275 | 9.37 | 0 | 0 |
| $\mathbf{2 1}$ | 6.98866 | 0,14309 | 0 | 0 | 13.21 |

Table 4.1 Mass participation factors
Out of the 100 modes that were analyzed in Ansys software for the eigen-value analysis, the seven modes mentioned above in Table 5.1 were chosen. Since the participating masses did not achieve the 5 percent threshold specified by NTC18 and also because the majority of the modes are local and not global enough to be of interest to us, these seven modes were chosen from a range of 1 to 21 characteristic modes of vibration. The seven modes have been summarized with the mode shapes.

### 4.2 Mode Shapes with Respect to Frequency

In the below it has been reported the mode shapes of each one of the seven modes.

Figure 4.2 Mode 2 Freq=2.53

Figure 4.3 Mode 3 Freq=3.20

Figure 4.4 Mode 7 Freq= 4.00

Figure 4.5 Mode 8 Freq $=4.42$

Figure 4.6 Mode 9 Freq $=4.45$

Figure 4.7 Mode 21 Freq=6.98

The main direction of the modes is shown in below Table 3.2.

| MODE | FREQUENCY ( Hz) | PERIOD (s) | DIRECTION |
| :---: | :---: | :---: | :---: |
| $\mathbf{1}$ | 2.45618 | 0,40714 | $1^{\circ}$ mode in X direction |
| $\mathbf{2}$ | 2.53911 | 0,39384 | $1^{\circ}$ mode in Z direction |
| $\mathbf{3}$ | 3.36930 | 0,29680 | $1^{\circ}$ mode in Y direction |
| $\mathbf{7}$ | 4.00873 | 0.24946 | $\mathbf{2}^{\circ}$ mode in X direction |
| $\mathbf{8}$ | 4.42008 | 0.22624 | $3^{\circ}$ mode in X direction |
| $\mathbf{9}$ | 4.70036 | 0.21275 | $4^{\circ}$ mode in X direction |
| $\mathbf{2 1}$ | 6.98866 | 0,14309 | $\mathbf{2}^{\circ}$ mode in Z direction |
| Table 4.2 Direction of modes |  |  |  |

The structure's mass participants in each direction were considered while choosing the vibration modes, and each of the 100 modes was assessed separately in order to extrapolate only those modes that involved global modes of vibration. Some modes may have significant levels of mass participations, but these numbers may have an impact on some local structural components. A few modes were consequently ignored because of that reason. Modal being applied has low fidelity and that the modal type also influences the values. The modes that we are primarily interested in for computation and structural reaction are those that have an impact on the global rather than the local.

## Chapter 5

## 5. Response Spectrum Analysis

Response spectrum analysis, a multimodal analysis, is used to assess the seismic performance of an existing structure. It is feasible to convert a highly complicated dynamic problem to a smaller and easier static problem using this strategy, which is still utilized and encouraged in many laws today. We may conceive of them as extremely basic independent oscillators when undertaking this type of study. It is feasible to define the acceleration using the response spectrum's proper period and to know the mass in the mode under discussion. As a result, calculating the static force in the modal form under consideration is simple.

We will assume that the structure has larger resistance in the elastic range and no ductile qualities based on the response spectrum analysis' evaluation with behavior factor $\mathrm{q}=1$, which means that the elastic spectrum coincides with the design spectrum. This is an unfavorable scenario because, while taking into consideration the structure's potential for plastic resistance, the acting accelerations will therefore be maximized rather than minimized.

Because not all these modes are active at the same time, the various forces caused by these individually available mods are not simply put together. A mathematical method is required since spectral curves are only designed to offer the highest value and are insufficient to determine the contributions of the various modes at a particular time. By assuming that the highest contributions from all modes occur at the same time, an upper bound is determined. The sum of absolute values can be used to combine contributions from all modalities. However, because it achieves an inflated value, it is not commonly utilized in sizing. [8]

Instead, it has been demonstrated that the value obtained in systems with discrete free vibration frequencies using the SRSS (square root of the sum of squares) method produces values that are extremely near to the time history domain solutions. With the Complete Quadratic Combination (CQC) method, the constraints of this rule may be removed, and this rule could also be utilized for systems with near free vibration frequencies. If the interplay of the modes is ignored, the CQC and SRSS rules provide the same outcome. There is no requirement for a dynamic computation in the time history domain with these combinations. However, when spectrum curves representing the dynamic features of the earthquake are employed, this approach is truly a dynamic method. In addition, as compared to time domain analysis, behavior spectrum analysis is far more convenient. [8] As a result, two effect approaches known as and CQC are used to combine them (perfect square combination).

Seismic stresses for each constituent in the structure may be computed using this approach. For various earthquake combinations, static stresses are also applied. When we look at it, we can see that the drag vector is defined, which is a vector that moves in three spherical directions with various densities at the same time.

The structure's key elements are then identified and bending, and shear force restrictions are implemented in the most vulnerable areas. Response spectrum has been obtained by using the software is called "SIMQKE_GR". Below parameters have been entered into the software.

Zone 4 calculated based on the site's geographic location.
Nominal life : 50 years
Class of use : 4 ( It is dependent on the degree of suffocation. Even in the case of a calamity, a public facility with significant strategic activities is classified as Class 4 . The fact that Torino Esposizioni is a pavilion capable of holding large-scale events justifies this option, and the prospect of employing this structure for civil protection reasons is not to be ruled out.)

Coefficient used (cu) : 2 [Directly related to the usage class. This option doubles the project's seismic action's return duration.]

Subsoil category : C [Medium-thickened coarse-grained soil layers having mechanical qualities that gradually increase with depth. There are no geological studies of any type accessible, however this category was chosen since a "gravel bank" is referenced in the calculation report while doing foundation inspections.]

Topographic category : T1 [For level terrain or slopes with less than a $15 \%$ average inclination.]

SLV is taken into account as a limit state. The ultimate limit state for the preservation of life, according to the studies, is regarded human.

Damping ratio: \%5 (0.05)
We assume a seismic project activity with a return time of 949 years and a construction reference period of 100 years, based on the given criteria. This means that the event's probability of occurrence for the life limit state is always $10 \%$, but it's prolonged for a reference period that's double what's regarded for a class 2 structure in this situation. As a result, the return period is defined as the inverse of the likelihood of the event occurring in a single year, whereas the probability $(10 \%)$ is relative to the reference period in question.

### 5.1 Selection of Critical Zones

All the structural elements are not taken into account for the previously mentioned combinations because Ansys Mechanical does not support automatic checks. We want to define a few particularly interesting parts of the structure in this paragraph. The analysis that has been done before allows for the identification of key locations among Pavilion C's primary structural elements. The most stressed macro-elements of Hall C are listed below, based on a precise study of each macro-element:

- The diagonal beam, the main rib of the vault, and the two horizontal braces of the arches all meet at the top of the inclined strut, which is a key location suffering external strain and internal compression, displaying significant stress levels.
- Long side arch: the most stressed area is at the strut's base, where the element is subjected to both external tension and internal compression. This structural element's midspan portion is the one that has the most displacement.
- Short side arch: The short side arch functions similarly to the long side arch, but with lower stress levels.
- Pavilion vault: stresses are concentrated in the lower half, near the skylight, where the void section of the diamond shape decreases collaboration between neighboring ribs, resulting in greater tension and compression values in the central zone immediately after the midspan on both sides. In compression, the four major ribs that correspond to the skylight and connect to the inclined strut are the most strained.

Figure 5.4 Critical sections
The results that have been taken from dynamic analysis comparing with the static anlaysis which has been done before, 11 elements and different parts of structure have been chosen. The elements that have been chosen are shown in Figure 6.4. The name of the elements which are defined by Ansys software.

EL_4676 is at the base of major ribs. It has been selected because of the normal stress at base and $\mathbf{E L} \_\mathbf{4 6 6 2}$ is the midpoint elements of major ribs. It has been selected due to bending moment and shear force which effect so much strain on major ribs

EL_1523 is the undulated slab of the internal frame. It has been chosen because of effectiveness of normal and bending moment on the long side of the beam.

EL_1753 is the base of the long side of arches and EL_1761 is the middle point of the long side arches. These are the most critical part of the structure that can have strains more than other part of structure.

EL_1841 is the base of the short side of the arches while EL_1847 is the midpoint of the short side arches.

EL_1921 is the base of the pier while EL_1917 is the middle point of the pier. The corner of the inclined pier is the critical point as well.

EL_8734 is the pillar close to the gallery side which EL_779 is the pillar at the side which is other side of gallery.

The critical elements which have been selected on software are reported by its properties in the below Table 6..1.

| ELEMENT <br> NUMBER | MATERIAL <br> TYPE | SECTION <br> NUMBER |
| :---: | :---: | :---: |
| $\mathbf{7 7 9}$ | 13 | 71 |

Table 5.5 Section sizes
After that, dynamic measures were taken into consideration for the most pressured locations. The dynamic evaluations performed were solely for the purpose of determining structural criticalities and high-risk zones.

Ansys software was used to do three assessments with a response spectrum with $\mathrm{q}=1$ shifting the direction of the seismic action. The primary stress zones were explored, and a comparison was conducted to see if they related to the static analysis's highlighted zones, and which, if any, would be the most vulnerable to damage.

Normal stress which is defined Fx in software, shear stress in the y and z directions which are defined SFy and SFz in software and bending moments in the y and z directions which are define My and Mz were the stress outputs for the three separate directions.

It may be recognized which structural elements are most impacted by the seismic activity by looking at the related deformed structure with total displacements in each direction

### 5.1.1 Displacement in X Direction

Figure 5.5 Total displacement in $X$ direction

| X_Displacement | $[\mathbf{m m}]$ |
| :---: | :---: |
| Ux | 13.65 |
| Uy | 3.99 |
| Uz | 12.34 |
| Usum | 15.85 |

Table 5.6 x direction displacement summary
We began by calculating the overall displacement in the x-direction, as shown in the diagram, and the most impacted region appears to be in the middle area of the corrugated floor (along the long length of the hall) near the vault, as well as the central area under the inclined arches. Both of these zones were previously identified as being at risk. In the locations recently examined, the overall displacement (USUM) combined with this direction is a significant entity, measuring roughly $16 \mathrm{~mm}(1.59 \mathrm{~cm})$.

### 5.1.2 Displacement in Y Direction

Figure 5.6 Usum dispalcement in Y direction

| Y_Displacement | [mm] |
| :---: | :---: |
| Ux | 9.68 |
| Uy | 8.42 |
| Uz | 6.92 |
| Usum | 11.32 |

Table 5.7 y direction displcement summary
The corrugated floor on the short side of the hall looks to be more significantly impacted in the y-direction. In this situation, the inclined arches are still engaged in considerable displacements, but there is less influence in the area of the long arch's midsection, but mostly in the area specified as 14 of the arch, compared to the prior direction. In this direction, the overall displacement is around $11.32 \mathrm{~mm}(1.13 \mathrm{~cm})$.

### 5.1.3 Displacement in Z Direction

Figure 5.7 Total displacement in $Z$ direction

| $\mathbf{Z}_{-}$Displacement | [mm] |
| :---: | :---: |
| $\mathbf{U x}$ | 0.694 |
| Uy | 0.845 |
| Uz | 0.599 |
| Usum | 0.845 |

Table 5.8 z direction displacement summary
The quantities fall dramatically in the z direction, barely surpassing one millimeter. Because z is not the major direction of seismic motion, it operates with lower order displacements than x and $y$. The four center sides of the corrugated floor, the pavilion vault at the central rib, and a portion of the roof of the side gallery are the parts most exposed in this example. In this direction, the greatest displacement is roughly 0.85 mm .

### 5.2 Seismic Stresses Calculation

The ANSYS mechanical 17.2 program is used to compute the seismic stresses completely automatically for each structural member. Considered is the soliciting seismic activity, which acts independently in all three directions. Three sets of stresses are determined in this manner, each one corresponding to a different direction.

The stresses in each structural component for each direction taken into consideration are output using a script made especially for this purpose. The values of the spectrum in terms of frequency and accelerations, the kind of combination to be utilized, and the number of modes to compute must all be specified in this set of commands.

The moment, shear, and normal values associated with each mode of vibration have been integrated using a statistical criterion: the NTC 2008 outlines two approaches for combining the effects of the various modes.
The first method, known as SRSS, calculates the combined effect by taking the square root of the total of the squares of the effects of the various modes:

$$
E_{d}=\sqrt{E_{1}^{2}+E_{2}^{2}+E_{3}^{2} \ldots E_{N}^{2}}
$$

where N is the number of ways to vibrate.
The CQC (complete quadratic combination) is used when the modal periods differ by less than $10 \%$ and contains a correlation coefficient between the distinct modes.

$$
\begin{gathered}
E_{d}=\sqrt{\sum_{i=1}^{N} \sum_{j=1}^{N} \rho_{i j} \cdot E_{i} \cdot E_{j}} \\
\rho_{i j}=\frac{8 \zeta^{2} \beta_{i j}^{3 / 2}}{\left(1-\beta_{i j}\right)\left[\left(1-\beta_{i j}\right)^{2}+4 \zeta^{2} \beta_{i j}\right]}
\end{gathered}
$$

where $\beta i j$ is the ratio between the inverse of the periods of each pair of modes $\mathrm{i}-\mathrm{j}(\beta i j=T j T i)$ and $\zeta$ is the viscous damping. Since there are modes that are extremely near to one another in the frequency domain, as was clearly evident during the modal analysis, the CQC combination approach is employed in the scenario at hand.

The data are collected and combined automatically using ANSYS mechanical APDL. The stated results were obtained straight from software.

Normal stress, bending stress in y and z directions, and shear stresses in y and z directions are characterized sequentially as Fx, My, Mz, SFy, SFz. All of the findings from each direction have been provided in the following chapters for the most critical components that have been taken into account and described before chapter in 6.2.

### 5.2.1 Seismic Action In X-Direction

The most significant stresses in the elements at risk are produced by the seismic activities occurring in the x-direction, which appear to have the greatest influence on the structure. In this instance, both the normal stress and the shear stress in the z and y directions appear to be particularly prevalent at the base of the inclined arches on the long side. On the other hand, it appears that the section at the base of the corner pier experiences more bending moment in the $y$ direction than it does in the $z$ direction at the base of the short arch.

### 5.2.2 Seismic Action In Y-Direction

The stresses in the y direction are calculated by considering just the spectral accelerations in the y direction. The arches at the base and the midpoints of the structure are the most affected. The normal and shear stresses are larger in these portions compared to the other parts because of the seismic applied in the y direction. Table 6.9 shows the results obtained by the program after CQC combination for the most critical parts. Following that, the results were plotted and reports were written.

### 5.2.3 Seismic Action In Z-Direction

The stresses in the z direction are determined by taking just the spectral accelerations in the z direction into account. Because $z$ direction isn't our major direction while seismic applied on structure ,it has not been reported significant effects on the structure. Table 6.10 shows the results obtained by the program after CQC combination for the most critical parts. Following that, the results were plotted, and reports were written.

## Chapter 6

## 6. Seismic Assessment

Prior to determining the seismic behavior of existing structures, it is important to identify the structural system aspects of the existing structures. Additionally, examining the building's construction history and learning about any prior damage, repairs, or modifications allows for the collection of crucial information. The project plan can be used to determine the existing structure; if not, survey studies can be used. The project plan can also be used to evaluate the strength of the structural materials used to build the structure, as well as the results of material tests and ground surveys. [9] The structural characteristics of existing engineering constructions should be accurately assessed. to ascertain the structural system qualities of the structures, which are unknown given the circumstances under which they were constructed in the past, and how much damage they sustained as a result of the events that transpired while they were in use (earthquakes, meteorological effects, fatigue, creep, etc.) [9] [10]

The critical sections which have been defined and mentioned before have been taken into account in order to analyze the seismic behavior of the structures. The cross sections of elements and material has been used for that element has taken from "Investigations on the structural criticalities of Pier Luigi Nervi's Hall C in the Turin Exhibition Center" academic master thesis which has been written by Virginia Sparascio. The reinforcement of the sections have taken from "Report 3: Torino Esposizioni, Salone C. Experimental investigations on structures".

### 6.1 Combinations of Actions

The seismic combinations are made by defining three drag vectors in the three stress groups that correspond to the three orientations. In the table below it is reported the case study as an combination of stresses that obtained. totally for each element there are 48 combinations of dynamic plus static analysis results and one has been considered only for the case of static analysis. Hence, 49 options have been considered for each element and each direction.

Table 7.1 indicates the combinations of seismic actions which has been taken into account while verifying the elements and it has been defined by case number as it shows in table from 1 to 24 cases for one direction since y and z directions have been considered the total permutations are 48 and one is evaluated by using only static analysis results or considering vertical actions on structure.

The seismic combinations are formed by creating three drag vectors based on the three stress groups associated with the three orientations. For instance, the most common earthquake combination X will be:
[Case 1] 1 $\mathrm{Ex}+0.3 \mathrm{Ey}+0.3 \mathrm{Ez}$
where Ei are the program's output stress groups. In order to enhance the impact, static stresses with their own sign are added to seismic stresses. The combination indicates that seismic action
have a 100 percent effect in the X direction, a 30 percent effect in the Y direction, and a 30 percent effect in the Z direction. Then a summary of these 3 direction results has been written and named case 1. The other combinations have been considered for each and every permutation obtained like case 1 . The results of all permutations considered for verification of pressoniflation and shear stresses for each and every critical element.

### 6.2 Verification

The bending and shear check is performed for each part in the selected critical elements which is shown in figure 6.4 chapter 6. It has been used the combinations of stresses indicated in Table 7.1. The mechanical properties of concrete and cross sections of elements which are defined in previous chapter have been taken from previous works which has been done on Turin exhibition center C Hall [11]. The steel mechanical properties are established based on information gathered through archives and publications on the materials used at the time [12] [13] , and the legislation in effect at the time of construction is utilized to categorize them [14]. The reinforcement quantities information are taken from report which is performed some destructive and non-destructive tests. [15]

Due to lack of information about the structure present regulations suggest that about resistances of material to be decrease by confidence factor which is defined 1.35 .

The studied analyses are utilized to determine where the structure has weaknesses in terms of static and dynamic capability in order to rationally lead and arrange the experimental testing. This allows us to zero in on certain regions of the structure and study them quantitatively using more precise models.

It is reported below for the analysis has been done step by step;

1. Stress calculations with respect to the combinations of static and dynamic actions which has been defined before
2. Sectional properties of the elements which has been reported before
3. Verification with bending-compression (presso flessione)
4. Shear verification using MATLAB code as well as Excel file
5. Bending Moment-Normal Forces interaction diagram [ $\mathrm{M}-\mathrm{N}$ ]

Excel file was utilized for the calculation, combination, and verification results. To utilize the final values for verifications, the solicitations collected in the preceding stage are merged as follows:

$$
\begin{gathered}
E_{d}=\left(\begin{array}{ll}
M_{i} & V_{i} \\
N_{i}
\end{array}\right) \pm\left(\begin{array}{ll}
M_{i} & V_{i} \\
N_{i}
\end{array}\right)_{C Q C} \\
E_{d, i+}=E_{S T A, i} \pm\left|E_{C Q C, i}\right|
\end{gathered}
$$

### 6.2.1 Assessment with Interaction Domain

The values which have been taken from combination of action have been used in order to check in interaction domain. It has been used the excel file which is provided by Prof. Alessandro Fantilli to check M-N interaction diagram.

For the assessment of the existing structure, we have to consider the biaxial bending and we can use a simplified way, by conducting the verification separately in each direction, with the uniaxial moment of resistance reduced by $30 \%$. It is shown below the critical section comparing with the interaction diagram. Then, it must be checked that The ratio between normal stressing and resistant stress of the concrete alone must be less than 0.65 .

$$
\frac{N_{E d}}{f_{c d} A_{c}} \leq 0.65
$$

The all-critical elements have been checked and verified all of with respect to the empirical formula.

### 6.2.1.1 EL 1753 (Long Archway At The Base)

Figure 6.1 Ell 1753 cross section
In the Figure 7.1 indicates the cross-section of element (El1753) which is represent C hall's long archway at the base point. It has been defined by 60 cm width and 115 cm in depth. The reinforcement quantities are $4 \Phi 26$ at the bottom and top , $7 \Phi 26$ at the side of the cross-sections. The concrete which has been used for the element is TIP680 which has 46 MPa characteristic strength and it has assumed that steel characteristic strength is 260 MPa from the report that has been written in 1950-1980. [13]

The below Table 7.2 and table 7.3 have been reported the static analysis and combination of actions with respect to the dynamic analysis results. The static analysis results have been taken from previous work which has been done before [11]. The combinations of actions have been done by using excel file.

|  | $\mathbf{N}[\mathbf{N}]$ | $\mathbf{M y}[\mathbf{N m}]$ | Ty [N] | Tz [N] | $\mathbf{M z}[\mathbf{N m}]$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Static analysis | -2590000 | 435762 | 223663 | -65398 | 899837 |

In the Table 7.2 can be seen that the normal force on the long archway at the base point is 2590 kN . The bending moment in y axis is 435 kN in z axis is about 900 kN which is double of the y axis. The shear forces are 223 kN and 65 kN in y and z axis respectively.

Table 6.3 EL1753 combinations results
Table 7.3 shows the results which has been obtained from the combination with respect to the static actions and dynamic actions.

Figure 6.2 Excel file input parameter

The values are in millimeter $(\mathrm{mm})$ and in the software it must been defined material properties which are $f_{c d}$ and $f_{y d}$ for concrete and steel, cross-section, stripes of reinforcement, reinforcement area and their location. After defining values, it has to run the macro excel file it will give general $\mathrm{N}-\mathrm{M}$ interaction diagram.

Figure $6.3 N$-My interaction domain diagram (EL1753)

Figure 6.4 N -Mz interaction domain diagram (EL1753)
In the Figure 7.3 and Figure 7.4 were shown the graphicaly results Normal Force-Bending moment interaction diagram with respect to the in $y$ and $z$ axis. In the graph demonstrate blue and red line which are obtained by the excel macro code and the green is shown the $70 \%$ of the general moment which is obtained by code. Because We must include biaxial bending while assessing the current structure, and we may simplify the process by doing the verification individually in each direction, with the uniaxial moment of resistance lowered by $30 \%$ as it mentioned before. The points which are purple, and blue represents the results of bending moment combinations with dynamic and static analysis which are totally 48 points. The orange point is represented the static analysis bending moment results.

In Figure 7.3, the bending moments derived from combination actions are expressed between the N-M interaction diagram, indicating that it is verified with regard to the y axis bending moment resistance. However, the result for z axis bending moments reported in Figure 7.4 are not totally verified since certain locations are outside of the defined graph. The pressure in z
axis is high for the base of the long archway and pressoniflation isn't verified for the element in z axis.

### 6.2.1.2 EL 1761 (Long Archway At The Middle Point)

Figure 6.5 Cross-section (EL1761)

EL1761 is defined code name to represent long archway at the middle point in the software. It has the same cross section with the long archway at the base point but with different reinforcement quantities. It has 60 cm width and 115 cm depth. It has $4 \Phi 26$ at the bottom and top as well at the side of the rectangular cross-section. It has $2 \Phi 26$ in each side of the cross section of element. The results which has been taking from static analysis has been reported in Table 7.5.

Table 6.6 Combination of actions results (EL1761)

Figure 6.6 N-My interaction domain (EL1761)

Figure 6.7 N-Mz interaction domain (EL1761)
In the Figure 7.6 is results which obtained from excel macro code by putting normal forces and bending moment which have been defined combination of actions. All points are between the graph which is defined $30 \%$ reduced bending moment resistance. Therefore, it has enough resistance in the $y$ axis with respect to bending moment combinations.

The Figure 7.7 is the results for the z axis normal forces- bending moment interaction diagram. The points are out of the graph which means that it's not verified with respect to pressoniflation. The results are expected the same as the EL1753 because the stress is on the long archway in base and in the mid-point are more or less same.

### 6.2.1.3 EL1841 (Short archway at the base)

Figure 6.8 cross-section (EL1841)
EL1841 is defined in the code to represent the short archway at the base point. It has defined as beam 188 element like others, and it is rectangular cross section which is 60 cm by 105 cm . it has $4 \Phi 20$ at the top and bottom. It has been placed $7 \Phi 20$ in each side of the element. The concrete cover is 3 cm . The concrete strength is 46 MPa and 260 MPa is the steel yielded strength.

| Static analysis | -1290000 | -241427 | 135171 | -64435.8 | 425833 |

Table 6.8 static analysis results (EL1841)
The Table 7.8 is shown the static analysis results. It has almost half stress values on the base of the short archway with respect to the long archway base point. The normal force is 1290 kN and shear forces are 135 kN 64 kN in y and z respectively. The bending moments are 241 kNm around y axis and 425 kNm around z axis which almost double in z axis.

Figure 6.9 N-My interaction domain (EL1841)

Figure 6.10 N-Mz interaction domain (EL1841)

In Figure 7.9 and Figure 7.10 are the graphs of $\mathrm{N}-\mathrm{M}$ interaction diagram for y and z axis. The combinations of Normal forces and bending moments are stated between the $30 \%$ reduced bending moment graph in the y direction. On the other hand, some points are out of the graph in $z$ direction graph which is shown in Figure 7.10. The element has no enough resistance for the z direction action of normal stresses-bending moment.

Table 6.10 checking Ned/(fcd*Ac)

### 6.2.1.4 EL1847 ( Short Archway in the middle point)

Figure 6.11 cross-section (EL1847)

EL1847 is defined for short archway in the middle point in the software code. It has the same cross-section, material properties and concrete cover like the base of the short archway element. The only difference with respect to the EL1841 is the reinforcement quantities. It has $4 \Phi 20$ in all side of the element. Table 7.11 which is below shows the static analysis values for the EL1847. The values are the more or less same as the base point of the arch.

|  | $\mathbf{N}[\mathbf{N}]$ | $\mathbf{M y}[\mathrm{Nm}]$ | Ty [N] | Tz [N] | Mz [Nm] |
| :---: | :---: | :---: | :---: | :---: | :---: |

Table 6.12 combination of actions results (EL1847)

Figure 6.12 N-My interaction domain (EL1847)

Figure 6.13 N-Mz interaction domain (EL1847)

Figure 7.12 and Figure 7.13 are the output of excel macro code and files which are the results for N-M interaction diagram. The cross-section, material properties are the same as the base point of the arch as well as the stresses act on the midpoint is the same as base point. Therefore, the results can be expected the same which is verified in y direction and hasn't enough resistance in $z$ direction.

### 6.2.1.5 EL1523 (Internal frame undulated slab)

Figure 6.14 cross-section (EL1523)
EL1523 is defined for the undulated slab internal frame in ANSYS software code. In reality it has wavy shape but in software it has been defined as rectangular cross-section with 70 cm by 90 cm . The reinforcements are assumed to be placed $6 \Phi 10$ at the bottom, $2 \Phi 10$ in the top and $1 \Phi 5$ at each side. The concrete and steel strength parameters are the same as arches. The concrete cover is assumed 3.5 cm . Table 7.14 is shown static analysis results for the undulated slab. It has been acted 1580 kN normal forces, 0.3 kN and 47 kN shear forces in y and z direction respectively. The bending moment in y direction is 224 kNm and 93 kNm in z direction.

Figure 6.15 N-My interaction domain (EL1523)

Figure 6.16 N-Mz interaction domain (EL1523)
Figure 7.15 and Figure 7.16 are the graph of interaction diagram with action of combinations in $y$ and $z$ direction. All the values are between the $\mathrm{N}-\mathrm{M}$ reduced $30 \%$ bending moment resistance graph .Hence the element has passed the pressoniflation which has enough resistance for the acting normal stress and bending moment.

### 6.2.1.6 EL4676 (Lateral rib_ at the base)

Figure 6.17 cross-section (4676)
EL4676 is the definition of code for the lateral rib of the C hall at the base point. It has defined 25 cm by 75 cm rectangular shape cross-section. The steel and concrete strength parameters are like the other elements as mentioned before. It has $2 \Phi 12$ at the bottom and top , $3 \Phi 12$ in each side. The concrete cover is 3.5 cm .

Table 7.17 is demonstrated the static analysis results which has been taken from previous works. Normal force is 1100 kN and shear forces are $4 \mathrm{kN}, 44 \mathrm{kN}$ in y and z direction respectively. The bending moment in y direction is 75 kNm and 3 kN in z direction.

Figure 6.18 N-My interaction domain (EL4676)

Figure $6.19 \mathrm{~N}-\mathrm{Mz}$ interaction domain (EL4676)
Figure 7.18 and Figure 7.19 are the output of macro excel file results with the combination of actions results. It is shown the N-M interaction diagrams which obtained in general values as well as reduced $30 \%$ bending moment resistance. All the 49 points which is defined for each direction with static analysis result and actions combinations are stated between the graph in $y$ and $z$ direction. Therefore, the lateral rib has enough resistance for the acting forces on the element with bending moment.

### 6.2.1.7 EL4662 (Lateral rib in the midpoint)

Figure 6.21 cross-section (EL4662)
EL4662 is defined for the lateral rib in the midpoint in the software code. It has the same cross-section, material properties, concrete cover with respect to the lateral rib at the base point.

Figure 6.22 N-My interaction domain (EL4662)

Figure $6.23 \mathrm{~N}-\mathrm{Mz}$ interaction domain (EL4662)
As it is shown in Figure 7.22 and Figure 7.23 all the values of Normal forces- Bending moments combinations are placed between the reduced bending moment resistance with respect to normal forces. Hence, The lateral rib in the midpoint has enough resistance for the acting axial forces and bending moment.

### 6.2.1.8 EL779 (External pillar at the base)

Figure 6.24 cross-section (EL779)
EL779 is represent the external pillar at the base point in the software code. It is defined crosssection beam which is 30 cm by 40 cm . The concrete parameters are different from the elements which is defined before. It has been defined for TIP500 concrete which has 26 MPa compressive strength. The steel strength parameters are the same as other elements which is 260 MPa . The concrete cover is 4 cm at side and 2 cm in the top and bottom. It has $2 \Phi 12$ in the top and bottom. Table 7.25 is shown the static analysis results,

|  | $\mathbf{N}[\mathbf{N}]$ | $\mathbf{M y}[\mathbf{N m}]$ | Ty [N] | Tz [N] | $\mathbf{M z}[\mathbf{N m}]$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Static analysis | -221980 | -1450.6 | -2394.3 | 1297.5 | -6105.5 |

Figure 6.25 static analysis results (EL779)
The axial force is 222 kN and shear forces are 2.4 kN 1.3 kN in y and z direction respectively. The bending moment in y direction is 1.45 kNm and 6.1 kNm in z direction.

Figure 6.26 N-My interaction domain (EL779)

Figure 6.27N-Mz interaction domain (EL779)
Figure 7.26 and Figure 7.27 are the N-M interaction diagrams for the external pillar at the base point with the combinations of normal forces and bending moments. In both direction the allcombinations values are between the reduced bending moment resistance -normal forces diagram. The external pillar has enough strength to resist against axial forces and bending moments.

### 6.2.1.9 EL8734 (External pillar in the gallery side)

Figure 6.28 cross-section (EL8734)
EL8734 is the name in code to represent the external pillar at the midpoint in the C hall gallery side. It has the same material properties and reinforcement bars like external pillar (EL779). It is 30 cm by 30 cm square cross-section. The concrete cover is defined 2 cm .

Table 7.24 is for the results of static analysis which is 109 kN axial force and 5.8 kN shear force in y direction , 0.11 kN in z direction. The bending moments are $0.13 \mathrm{kNm}, 7.23 \mathrm{kNm}$ in y and z axis respectively.

Figure 6.29 N-M interaction diagram (EL8734)
Figure 7.29 is the graph which is represent $\mathrm{N}-\mathrm{M}$ interaction diagram for the y and z directions. The cross-section of the pillar is defined square therefore it can be using the same interaction diagram for both directions. In the graph can be seen some points are outside of the reduced bending moment, normal forces interaction diagram. Therefore, the pillar hasn't enough resistance for the acting normal forces and bending moments.

### 6.2.1.10 EL1921 (Central Arches_at the base)

Figure 6.31 cross-section (EL1921)
EL1921 is the name in software code for the central arches foot at the base point. It has been defined 70 cm by 138 cm rectangular cross-section shape. It has $2 \Phi 16$ reinforcement bar at the bottom and $3 \Phi 16$ on the top. $1 \Phi 16$ at each side in the middle. The concrete cover is 4 cm .

Table 7.26 is shown the static analysis results for the EL1921. Normal force is 218 kN and 25.7 kN shear force in y direction 15.5 kN shear force in z direction. The bending moments are 25 kNm and 68.4 kNm in y and z direction respectively.

Figure 6.32 N-My interaction domain (EL1921)

Figure 6.33 N-Mz interaction domain (EL1921)
Figure 7.32 and Figure 7.33 are the output for macro code to make N-M interaction diagrams with the results of actions of combinations. The values of normal forces and bending moments that obtained by combination of static analysis and dynamic analysis are placed between reduced bending moment- normal forces interaction diagram. Therefore Central arches at the base point has enough resistance for the acting forces.

### 1.1.1.1 EL1917 (Central Arches_in the middle point)

Figure 6.34 cross-section (EL1917)
EL1917 is the code name for the central arches in the middle point which has the same crosssection with EL1921. It has also same material properties and reinforcements bars. Table 7.29 is shown the static analysis results for the EL1921. Normal force is 210 kN and 25.7 kN shear force in y direction 75.34 kN shear force in z direction. The bending moments are 206.7 kNm and 34.413 kNm in y and z direction respectively.

Table 6.30 combination of actions results (EL1917)

Figure 6.35 N-My interaction domain (EL1917)

Figure 6.36 N-Mz interaction domain (EL1917)
Figures 7.35 and 7.36 show the output of macro code for creating N-M interaction diagrams with the consequences of combinations' actions. The values of normal forces and bending moments obtained from a combination of static and dynamic analysis are shown on a reduced bending moment-normal forces interaction diagram. As a result, the central arches in the middle point provide enough resistance to the active forces.

### 6.2.2 Shear Assessment

Structures were frequently examined in the early stages of structural assessment practice based on the design need. Generally, design codes were employed, and if a given construction complied with the code, it was considered as safe. It was later shown that such a simple technique might result in a conservative evaluation result in many cases, particularly when it came to shear capability. This occurs because the ancient structures were created in accordance with the old design codes, whilst the evaluation is carried out in accordance with the current rules. In terms of shear, the present regulations are more stringent than the earlier ones in various ways. [16]

It's inaccurate assumption of linear longitudinal stress state in fractured concrete This is due to the fact that shear behavior cannot be generalized under all situations. It is extremely sensitive to changes in factors such as beam section, shear span ratio, and steel reinforcement. It is even possible for seemingly similar beams to behave differently. This is because shear behavior and strength are impacted by multiple parameters, and there are likely parameters or correlations between these parameters that have yet to be discovered. [17]

The design shear resistance $\mathrm{V}_{\mathrm{Rd}}$ of structural members with shear reinforcement must be assessed using an appropriate lattice structure. The ideal lattice's resistant elements are the transverse reinforcement, longitudinal reinforcement, compressed concrete stream, and inclined core struts. Brittle failure, the most hazardous outcome of shear motion, can occur.

The shear assessment updated code is shown below which provided by Italian code; [18]
Tension-shear: assess the shear reinforcement

$$
V_{R s}=0.9 d \frac{A_{s w}}{s} f_{y d}(\operatorname{cotg}(\alpha)+\operatorname{cotg}(\theta)) \sin (\alpha)
$$

Compression-shear: assess the concrete

$$
V_{R c}=0.9 d b_{w} \alpha_{c} v f_{c d} \frac{\operatorname{cotg}(\alpha)+\operatorname{cotg}(\theta)}{1+\operatorname{cotg}^{2}(\theta)}
$$

Resistance shear of a section

$$
V_{R d}=\min \left(V_{R s}, V_{R c}\right)
$$

Where

$$
\begin{aligned}
& \alpha=90^{\circ} \text { and } \theta=45^{\circ} \\
& \alpha_{c}\left[\begin{array}{lll}
=1 & \text { if } & N_{e d} \geq 0 \text { (tension) } \\
=1+\frac{\sigma_{c p}}{f_{c d}} & \text { if } & 0 \leq \sigma_{c p} \leq 0.25 f_{c d} \\
=1.25 & \text { if } & 0.25 f_{c d} \leq \sigma_{c p} \leq 0.5 f_{c d} \\
=2.5\left(1-\frac{\sigma_{c p}}{f_{c d}}\right) & \text { if } & 0.5 f_{c d} \leq \sigma_{c p} \leq f_{c d}
\end{array}\right. \\
& \begin{array}{l}
\sigma_{c p}=\frac{\left|N_{c d}\right|}{A_{c}} \\
v=0.5
\end{array} \\
& \begin{array}{l}
A_{s w}=2 \frac{\rho_{s w}^{2}}{4} \\
\alpha: \text { angle of inclination of the transverse reinforcement with } \\
\text { respect to the axis of the bearn } \\
b_{w}: \text { minimum section width (in mm) } \\
\theta: \text { inclination of concrete struts with respect to the beam axis }
\end{array}
\end{aligned}
$$

Shear force calculations were performed using MATLAB code and the current Italian code. The design shear force and resistance shear force were compared using an excel spreadsheet. Each critical element's results have been provided. The action of combinations results and static analysis results (totally 49 values for each direction ) are taken into account while doing verification of shear assessment. The outcomes are addressed in following.

## EL1753 (Long archway at the base)

For the long archway at the base, it has been used $\Phi 8$ transverse rebar with 20 cm space. The results which are provided by MATLAB code and excel file is shown in Table 7.32.

Table 6.32 shear assessment verification results (EL1753)
The resistance shear force is the minimum value for the shear resistance in concrete and steel. The shear resistance is provided by steel resistance shear force which is about 85 kN . Most of the shear values in y direction aren't verified. Because the shear stress which is applied is lower than the resistance shear stress which elements can carry. On the other hand, shear stress in z direction have been verified for all action of combinations values as well as static result value.

## EL1761 (Long archway in the middle point)

It has been used the same transversal reinforcement like long archway at the base (EL1753).

Table 6.33 shear assessment verification results (EL1761)
Table 7.33 is shown results for shear forces which is provided by excel file and MATLAB code. The shear resistance is minimum for the steel shear resistance which is the same as EL1753 ( $\left.\mathrm{V}_{\mathrm{Rd}}=85 \mathrm{kN}\right)$. It has almost the same effect as the long archway at the base in y direction. The element doesn't have enough resistance for some values in z direction as well.

## EL1841 (Short archway at the base)

The transversal reinforcements which are used for the short archway at base is the same as long arches with the same space.

Table 6.34 shear assessment verification results (EL1841)
Table 7.34 is reported values for the shear forces resistance and action of combinations results. The shear resistance is minimum for the steel shear resistance which is $\mathrm{V}_{\mathrm{Rd}}=77.3 \mathrm{kN}$. The element isn't verified in y direction with comparing most of the values. But there is only one value isn't verified about shear resistance in z direction.

## EL1847 (Short archway in the middle point)

It has been used the same transversal reinforcements and spacing like long arches.

Table 6.35 shear assessment verification results (EL1847)
The values for shear force resistance and action of combinations are provided in Table 7.35. The shear resistance is minimum for the steel shear resistance which is the same as EL1841 $\left(\mathrm{V}_{\mathrm{Rd}}=77.3 \mathrm{kN}\right)$. The element is validated in the y direction by comparing all of its values. On the other hand, 7 values for shear resistance in the z direction have not been validated.

## EL1523 (internal frame undulated slab)

It is made assumption $\Phi 5$ transversal reinforcement with 20 cm has been used for undulated slab due to its wavy cross section shape.

Table 6.36 shear assessment verification results (EL1523)
The values for shear force resistance and action of combinations are provided in Table 7.36 for the undulated slab. The shear resistance is minimum for the steel shear resistance which is $\mathrm{V}_{\mathrm{Rd}}=25.7 \mathrm{kN}$. The element isn't verified in the y direction by comparing most of values. On the other hand, all the values for shear resistance in the z direction have been validated.

## EL4676 (Lateral rib at the base)

It is used $\Phi 6$ transversal reinforcement with 20 cm has been used for lateral rib at the base.

Table 6.37 shear assessment verification results (EL4676)
The values for shear force resistance and action of combinations are provided in Table 7.37 for the lateral rib at the base. The shear resistance is minimum for the steel shear resistance which is $\mathrm{V}_{\mathrm{Rd}}=54.2 \mathrm{kN}$. The element is verified in the y direction by comparing most of values. On the other hand, some actions combinations shear forces which are provided while in x and y direction $100 \%$ effected loads with respect to static analysis results aren't verified in z direction.

## EL4662 (Lateral rib in the midpoint)

It has been used same cross-section and transversal reinforcement as rib at the base.

Table 6.38 shear assessment verification results (EL4662)
The values for shear force resistance and action of combinations are provided in Table 7.38 for the lateral rib in the midpoint. The shear resistance is minimum for the steel shear resistance which is $\mathrm{V}_{\mathrm{Rd}}=54.2 \mathrm{kN}$. (it's the as the base point). The element is verified in the y and z direction by comparing most of values.

## EL779 (External pillar at the base)

It is assumed that for the external pillar transversal reinforcement is $\Phi 6$ with 20 cm space as lateral rib.

Table 6.39 shear assessment verification results (EL779)
Table 7.39 shows the values for shear force resistance and action of combinations for the lateral rib in the midway. The steel shear resistance is minimal, with VRd $=15.3 \mathrm{kN}$. By comparing all values, the element is validated in the y and z directions.

## EL8734 (External pillar in the gallery side)

It is assumed that for the external pillar transversal reinforcement is $\Phi 6$ with 20 cm space as external pillar EL779.

Table 6.40 shear assessment verification results (EL8734)
Table 7.40 shows the values for shear force resistance and action of combinations for the lateral rib in the midway. The steel shear resistance is minimal, with VRd $=21.2 \mathrm{kN}$. By comparing all values, the element is validated in the y and z directions.

## EL1921 (Central Arches at the base)

It is taken transversal reinforcement is $\Phi 6$ from report which has been done before with 20 cm space is assumed.

Table 6.41 shear assessment verification results (EL1921)
Table 7.41 shows the values for shear force resistance and action of combinations for the lateral rib in the midway. The steel shear resistance is minimal, with $\mathrm{VRd}=4.2 \mathrm{kN}$. Most of the values aren't verified in $y$ and $z$ direction.

## EL1917 (Central Arches in the middle point)

It is taken transversal reinforcement is $\Phi 6$ from report which has been done before with 20 cm space is assumed as EL1921.

Table 6.42 shear assessment verification results (EL1917)
Table 7.42 shows the values for shear force resistance and action of combinations for the lateral rib in the midway. The steel shear resistance is minimal, with VRd $=4.2 \mathrm{kN}$. Most of the values aren't verified in $y$ and $z$ direction.

## Chapter 7

## 7. Discussion of the Results

Seismic assessment of Turin exhibition center C Hall has been done with respect to axial forces, shear forces and bending moments in the most 11 critical elements of structure. These critical sections are arches which in both side, pillar in both side, lateral rib, and internal undulated slab. Each of these sections have different seismic response. In below it's been discussed the response of these elements separately. In Figure 7.1 and Figure 7.2 are shown the elements which not verified in terms of $\mathrm{N}-\mathrm{M}$ interaction diagram and shear assessment, respectively. The long and short arches are the most stressed part which haven't pass the verification with respect to the $\mathrm{N}-\mathrm{M}$ interaction diagram. On the other hand, most of the elements don't pass the shear verification. Because it has been used the different steel type for stirrups which aren't allowed to use in current code and the space between stirrups are 20 cm which is in all part of columns. The other problem is that we make some simplification and have the low fidelity model which isn't given accurate results. The shape of the elements are different in reality and we make simplified it whole structure is beam elements.

Figure 7.1 Non verified section with respect to N-M interaction diagram

EL1753

Figure 7.2 Non verified sections with respect to shear assessment

### 7.1 Long side Arches

In terms of seismic actions, the arches of C Hall are the most essential structural element. Because the most stressed location is at the strut's base, where the element is subjected to external tension and internal compression. In prior work, the arches were statically examined, and the base and midway of the arches were taken into consideration. When compared to the other elements, the base of the arches has the most shear stress. This is defined as EL1753 in code. The transversal reinforcement in the y direction is not validated due to shear stress, and
the normal force-bending moments interaction diagram in the z direction is not verified as intended. $\Phi 8 / 20$ has been utilized for transversal reinforcement to withstand severe shear stress. In terms of shear evaluation, however, the midpoint of the arches is not verified in both directions. It is possible to shorten the space between transversal reinforcement to enhance shear resistance, or it is possible to use better steel with higher strength values. The bending moment can be reduced by changing the cross-section size or increasing the concrete strength by utilizing a different concrete type. The acquired results are not high fidelity, hence further analysis and experimental data should be collected to better understand the situation.

### 7.2 Short side Arches

Short side of arches has been acted like long side of arches. The results are showing with less stress on the short side, but it is also not verified like long side of arches. It has been defined less cross-section and decrease the steel strength parameter. In the long side it has been used $4 \Phi 26$ in top and bottom and 7Ф26 in side of elements while in short side it has been used Ф20 instead of $\Phi 26$. The transversal reinforcements are the same as long side of arches.

### 7.3 Internal frame undulated slab

The interior frame of the undulating floor, formed by the perimeter beams, is subjected to normal stress and bending moment at the centre of the long side. In real cross-section of the undulated slab It has wavy shape of beam and longitudinal reinforcements are $3 \Phi 10$ and $2 \Phi 12$ in the bottom, $2 \Phi 5$ in the side of cross-section and $6 \Phi 5$ at the top. It has been used also wire mesh with the concrete which is called ferrocement. In the report it has been simplified by 70/90 rectangular cross-section by putting $6 \Phi 10$ at the bottom, $2 \Phi 5$ in the side of cross-section $2 \Phi 10$ in the top. The transversal reinforcement has been defined $\Phi 5$ as its written on report.

### 7.4 Lateral rib

Normal stress near the base and bending moment and shear around the midway heavily loaded the primary ribs. It has been selected as critical section the base and midpoint of the rib. Main ribs in midpoint has been verified in point of view interaction diagram as well as shear assessment. On the other hand, the base of the rib isn't verified in the $z$ direction shear stress. For the element which is defined EL4662 and EL4676 has been assumed $\Phi 6 / 20$ tranversal reinforcement as the pillar.

### 7.5 Pillars

Because of the highest normal stresses indicated by static analysis, the pillar closest to the gallery side (EL8734) and the pillar closest to the structural middle (EL779) have been classified as critical elements. The pillars' evaluation has been confirmed using the interaction diagram and shear assessment. The pillars are strong enough to support the weight that they should.

## Chapter 8

## 8. Conclusion

The purpose of this thesis was to comprehend the structural behavior of Hall C at the Torino Exhibition Center which is designed and constructed between 1948 and 1950 by engineer Pier Luigi Nervi, it is one of the greatest landmarks of twentieth-century cultural heritage, containing a significant number of revolutionary building techniques and materials such as ferrocement, which Nervi invented. The suggested low-fidelity model has enabled extrapolation and analysis of data inherent in the static and, more importantly, dynamic behavior of the structure in issue.

The determination of the seismic performance of the Turin exhibition center is examined in this research. The eigen-value and response spectrum analysis of the structure was performed by transferring the structure's three-dimensional model from AutoCAD 3D to ANSYS Mechanical APDL.

In the plugging, the model was assumed without mass, and 100 vibration modes were retrieved in this manner. The modal analysis indicated the modes of vibration with the greatest effect on the structure, and 7 modes were chosen from 21 characteristic modes since current code states that the minimum participation factor must be larger than $5 \%$. It was discovered that the first and third modes had the most participants.

A simplified analysis with response spectrum and behavior coefficient $\mathrm{q}=1$ was performed to define and perform dynamic analysis. The stresses and displacements were obtained from software and integrated using the CQC combination method. Instead of inspecting every section of the structure, 11 critical elements were chosen to characterize all the structure's behavior in terms of dynamic and static analysis. The selection of most critical elements are the base and middle of the arches on both long and short side, the base and middle of the inclined corner pillars, the middle of the internal undulated slab, and the lateral ribs at the base of the vault, as well as the lateral ribs on the gallery side.

Following that, the response spectrum data, which include axial stresses, shear stresses, and bending moments for each critical element, were integrated with static analysis results from a previous thesis. The cross-section and material parameters were obtained from prior study, and the reinforcement information was derived from a previous experimental report. Using the excel file, $\mathrm{N}-\mathrm{M}$ interaction domain diagrams were evaluated, and 30 percent lower bending moment owing to existing structure is suggested in present code with 48 values of combination actions and 1 value with only static analysis. As a consequence, 49 points in the interaction diagram were examined in each direction for each critical element. The shear assessment for each critical element and each combination action was checked using excel and MATLAB code.

Complex structures, such as the Turin exhibition center, need an in-depth seismic assessment since, even if they are located in areas with low seismic risk, this variable might lead to significant issues created by the work's original idea. In terms of preserving historical
structures, transmitting all work done to the other generations and developing a dialogue space would surely advance the history. Because each structure has its own unique aspects, it exhibits a variety of architectural and engineering characteristics. As a result, every structure investigated, and every type of structural challenge faced will throw a bit lighter on the engineers who is working on this topic.
