#### Abstract

In Italy, approximately two-thirds of all crashes occur in urban areas, so identifying roadway and traffic factors that influence crashes occurring in such a context is an important area of research. According to the literature, there were no previous studies about parameters influencing crashes occurring in Italian urban areas, and in particular in Turin. This study involves developing safety performance functions (SPFs) for road segments in the city of Turin, including speed and geometric variables as main covariates in the model. The SPF is a mathematical regression model that predicts the crash frequency for road segments and intersections. Also, SPFs are an essential tool for conducting network screening studies and evaluating road safety improvements' effectiveness.

In this study, the negative binomial distribution was used to model crash frequency. In fact, crashes are rare and random events in a statistical sense and can be modelled as count data accounting for overdispersion. The overdispersion parameter represents the degree of overdispersion in a negative binomial model. Generalized Linear Modelling (GLM) was used to estimate regression parameters of the SPF. Two different types of SPFs were developed to identify influencing factors on crash frequency; in the first type, the operating speed (V85) and average speed (V50) of each lane of the road were estimated by using a model proposed by Bassani et al. (2014). In the second type, geometric variables such as median (M), parking lane (PL), access points density (ACD), driveway (DD), and pedestrian crossing density (PCD). Based on the results, a low correlation was found between speed and crash frequency. In addition, based on the literature, the probability of crash occurrence should increase by increasing speed, but the results showed an opposite behaviour in this specific case study. Among geometry features, access density and driveway density are the most influential factors on crash occurrence.

Considering that predictive road safety analyses were mainly conducted in North American, where functional and geometrical features are different from Italian roads, this study can be considered as a step forward to predict crash frequencies of Italian urban roads.

KEYWORDS: SPFs, Average speed, Operating Speed, AADT, Length.

## Chapter 1

## 1 Introduction

According to the World Health Organization website (2020), more than 1.35 million individuals are killed on roads worldwide every year due to road crashes. In addition, between 20 and 50 million more people suffer non-fatal injuries, with many incurring a disability because of their injury. Both fatal and non-fatal crashes will cost more than 1.8 trillion dollars between 2015-2030 years. But this massive amount of money does not include the suffering of individuals involved in accidents and the pain of family and friends. These irreversible effects of crashes on the society, economy, and health of the injured individuals cause road safety to be one of the main study topics. Although inhibiting collisions is somehow impossible, reducing the number and severity of crashes is a reasonable approach. But which road can be identified as unsafe, and what is the best method to identify some locations as unsafe? In the past, road agencies used a subjective view to identify hazardous locations by measuring the absolute number of crashes at locations or the ratio between crashes and Traffic volume. However, in recent years, researchers have tried to understand the reason for crashes. With this new approach, by evaluating influential factors on crash frequency, road agencies can act against factors causing unacceptable crash frequency (Tegge et al., 2010).

### 1.1 Terminology

This section presents essential terminologies, which are used in this thesis. Crash refers to a collision between two vehicles or a vehicle and any object or road user that can cause material damage or physical damage to people.

The KABCO scale is used by Highway Safety Manual (2010) for ranking crash severity. According to the KABCO scale, there are five categories for crash severity, which follows:

- K-An injury that results in death is a fatal injury;
- A - An injury, other than the K category that the injured person cannot walk, drive, or normally continue after the injury occurred is an incapacitating injury is any injury;
- B - The injury, other than K and A categories, that is evident; to observers at the place of the crash in which the injury occurred is non-incapacitating evident injury;
- C-Any injury reported or claimed that is not inside the above-mentioned categories and includes the claim of injuries not evident is a possible injury;
- O-No Injury includes Property Damage Only (PDO) crashes.

The Italian policy considers three categories that can be obtained by regrouping the KABCO in three classes: K as a Fatal class, A, B, and C as an Injury class, and O as a PDO class. The last class of collisions type is not included in the official Italian road crash database.

Crash frequency refers to the number of crashes occurring in a specific period at a particular intersection or along a road segment. According to HSM (2010), a safety performance function refers to a mathematical regression model for road segments and intersections that predicts crash frequency per year \# as a function of traffic volume and, in some cases, roadway or intersection characteristics (e.g., number of lanes, traffic control, or type of median).

In this study, intersection refers to an area in which two or more roads meet each other. A roadway segment refers to a road portion between two intersections. Access point refers to a roadway where it meets a secondary road, and vehicles can enter the roadway or exit. The intersection of them is typically not signalized. A driveway access point refers to the point where a roadway meets a private road of a private area or a building.

Finally, operating speed (V85) refers to the 85th percentile of a sample of observed speeds that drivers operate in free-flow conditions. Average speed (V50) refers to an average observed speed in a section where drivers operate in free-flow conditions (Bassani et al., 2015).

### 1.2 Background

Due to the harmful effects of crashes, transportation safety has become an essential topic among transportation engineers. The main goal is to understand the reason for crashes and implement suitable strategies to make roadways safer. Observational studies evaluate the effectiveness of road safety engineering countermeasures. In observational studies, crash data and information on the roadway characteristics such as AADT, grade, median type, etc., are analysed statistically to find any correlation between crash frequency and influential factors. Safety Performance Functions (SPFs) provide a statistical relationship between the predicted number of crashes per specific period and roadway characteristics. Since intersections and road segments are entirely different, different SPFs are needed to predict their crash frequencies. For instance, to develop SPFs of road segments, characteristics such as AADT, length, lane width, median width, etc., are used. At the same time, SPF for intersections depends on other factors such as AADT for both legs, type of intersection, turning lane, etc.

### 1.2.1 Safety Performance Functions

SPFs can be developed for different road types (i.e., rural roads, urban arterials, and freeways and elements (i.e., tangent, curves, intersections, etc.). Independent variables considered in a model should have a reasonable correlation with crash frequencies to develop an SPF. The best model is an SPF that best predicts crashes and shows a logical connection between the independent variables and the predicted value. However, because of limited time and resources, analysts use a limited number of variables for their SPFs.

Many studies were done on Safety Performance Functions (SPFs) to find a reasonable correlation between crash frequency and road- and traffic-related variables. Mayora et al. (2003) claimed that the highway variables with the highest correlation with crash rates in Spain's two-lane rural roads are: access density, average sight distance, average speed limit, and the proportion of no-passing zones. Greibe (2003) found that explanatory variables describing the road environment, number of minor side roads, parking facilities, and speed limit proved to be significant variables for predicting the crash frequency of road segments. Sawalha et al. (2001) indicated that section length, traffic volume, unsignalized intersection density, driveway density, pedestrian crosswalk density, number of traffic lanes, type of median, and land use type significantly affected accident occurrence. Cafiso et al. (2010) recommended three models based on statistical significance and goodness of fit indicators: the first includes only the exposure variables, length, and traffic volume, the second one provides length, traffic volume, driveway density, curvature ratio, and the standard deviation of the operating speed profile, and the third one includes length, traffic volume, driveway density, roadside hazard rating, curvature ratio and the number of speed differentials higher than $10 \mathrm{~km} / \mathrm{h}$. Marizwan et al. (2013) concluded that increased access points per kilometre and the average traffic volume are highly associated with increased motorcycle fatalities per kilometre. Sacchi et al. (2015) estimated that when the predicted traffic conflicts increase $1 \%$, predicted collisions increase $0.8 \%$. Mehta et al. (2013) concluded that the SPF, which estimates the mean crash frequency as a function of annual average daily traffic, segment length, lane width, year, and the speed limit, was the best one. Reddy Geedipally et al. (2017) found that the skid number variable is statistically significant, besides traffic volume, curve radius, and cross-sectional widths.

Some studies were done to evaluate how speed affects crash frequencies. Garber et al. (2000) concluded that there is a relationship between crash rates and the independent variables of the standard deviation of speed, mean speed, and flow per lane. On the one hand, Kockelman et al. (2007) concluded that there is no evidence to support a hypothesis that speed conditions influence crash occurrence. On the other hand, Quddus (2013) studied a series of relationships between segment-level average speeds, speed variation, and accident rates based on nonspatial and spatial statistical models using a panel data set obtained from a significant road network around London. Also, Xu et al. (2019) found that a more significant spatial and temporal speed variance increases the probability of crashes on an urban expressway. These contradictions may need further analysis to clarify the possible relationship between speed and crash frequencies. Moreover, these studies used different methods to collect data related to speed for estimating speed or speed variance, so that this reason can be the nature of these contradictions. According to Subasish et al. (2021), the increased variability in hourly operating speed within a day and monthly operating speeds within a year are both statistically significant for modelling crash frequency.

### 1.2.2 Negative Binomial Distribution

As far as the approaches, the Poisson model has been at first utilized in the SPF assessment since the crash frequencies are non-negative integers (Lord et al., 2010). Nonetheless, the Poisson model has its limitation distribution of data - the variance of the data is constrained to be obliged to be equivalent to the mean. This limitation may be problematic as the variance of crash data is normally greater than the mean (overdispersed data) (Washington et al., 2011).

According to the HSM (2010), SPFs are calibrated via Generalized Linear Model (GLM) using observed crash occurring data collected over several years at intersections or road segments with similar characteristics and containing a wide range of AADTs. The regression parameters of the SPFs are defined by assuming that crash occurrence follows a negative binomial distribution. Since crash is a rare event on roadways that exhibit significant overdispersion, the negative binomial distribution more accurately models the crash frequencies associated with road segments and intersections (Persaud, 2001). Hence, because observed accident data are overdispersed, the negative binomial distribution is preferred over the Poisson distribution. (Harwood et al., 2000).

To represent the degree of overdispersion in a negative binomial model, the overdispersion parameter is estimated. If the value of the overdispersion parameter increases, the crash data will vary compared to a Poisson distribution with the same mean. (HSM, 2010)

### 1.3 Objective and Scope of Study

In Italy, approximately two-thirds of all crashes occur in urban areas, so identifying roadway and traffic factors that influence crashes occurring in such a context is an important area of research. According to the literature, there were no previous studies about parameters influencing crashes occurrence in Italian urban areas, and in particular in Turin. This study involves developing safety performance functions (SPFs) for road segments in the city of Turin, including speed and geometric variables as main covariates in the model. In this study, crash frequencies are modelled only by negative binomial regression. The degree of overdispersion in a negative binomial model is represented by the overdispersion parameter. To calibrate SPFs, Generalized Linear Modelling (GLM) was used because of the discrete nature of crash frequency. Two different kinds of SPFs for selected segments of the Turin road network were calibrated considering a time framework of 5 years (2012-2016). Initially, the first group of SPFs was calibrated by using the Average Annual Daily Traffic (AADT), segment length, the Operating speed (V85), and Average Speed (these speeds were estimated using a Speed Model based on the geometrical characteristics of the road) as explanatory variables. Furthermore, the second group of SPFs was calibrated using the Average Annual Daily Traffic (AADT), the length of the segment, and geometric characteristics variables.

Chapter 2 is devoted to data collection and methodology. Then, the results of the models are presented in chapter 3 . In addition, chapter 4 consists of summaries and conclusions. Finally, references and appendixes, which contain tables of the data, are the last part of this manuscript.

## Chapter 2

## 2 Database and Methodology

This chapter is separated into two main parts; the first part is related to the database used in this thesis; the second part is associated with the methodology used to calibrate SPFs.

### 2.1 DataBase

In this study, QGIS (version: 3.4.4-Madeira) was used to organize, analyze and represent spatial data related to road network AADT, and crash data. In the following parts, the procedure of collecting and managing the database is discussed.

### 2.1.1 Road Network

Some roads of Turin were selected as a case study and, the selection of roads was made in two phases. In the first phase, 12 roads were selected, and in the second phase, five other roads were added to the sample. The summary statistics of the investigated road are reported in Table 2-1. The whole road network of Turin is shown in figure 2-1. After the selection of roads, their segmentation was the next primary step. According to the HSM (2010), the segmentation process produces road segments with different lengths by considering that they are homogeneous with respect to traffic volumes, roadway design characteristics, and traffic control features.

Table 2-1 Summary statistics of the road investigated network.

| \# | Road name | Total number of segments | Segment Length[km] |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Figure 2-1 Total Road Network. Red roads belong to the first sample, and the yellow ones belong to the second sample.
In this study, the roads were segmentized when there is a traffic light, and there is a change in AADT along the road. The definition of the segment length in the HSM (2010) was considered to identify the length of each segment. According to Figure 2-2, the segment length $(\mathrm{L})$ for a single homogenous roadway segment is the length of the road between two intersections. According to Figure 2-3, the distance between centres of two intersections controlled by traffic lights was considered road segment length. The result of segmentation is in Appendix 2. (Table A.2)

Figure 2-2 Definition of Segment Length. Taken from (HSM- 2010)

Figure 2-3 An example of roadway segmentation.

### 2.1.2 AADT

5 T - Telematic Technologies for Traffic and Transport in Turin S.r.l company provided the vehicle flow data used. The 5T metropolitan system is one of the most vital European mobility management systems based on ITS and includes nine subsystems, including UTC (Urban Traffic Control), which deals with traffic light regulation in agreement with local vehicle flow measures. The system currently operates on 330 traffic lights at intersections, with 2754 traffic detection units (loops), 1264 of which are not perfectly functioning (Masci et al., 2015).

Inductive sensors are near the intersections and detect the outgoing vehicular flow. Flow data is collected every minute and then averaged every 5 to obtain an aggregate flow rate of 5 minutes. By analysing the collected data and considering data of 365 days in a year, the AADT value was calculated along each direction of travel, so the AADT of both directions was summed to find the AADT of the roads. AADT data was provided for six years (20112016) in the shapefile used in QGIS.

According to Table 2-2, by considering the mean and standard deviation of AADT, there was no consistency in AADT data during years on some roads. For example, the mean and standard deviation of Via Filadelfia in 2012 are 8448 and 4776, respectively. In the following year, 2013, and they increased to 21456 and 24912. Then, they decreased to 14643 and 17488 in 2014. These kind of AADT fluctuations during years are suspect, so a method is needed to identify road segments which are outliers and eliminate them from the sample.

Table 2-2 Summary statistic of AADT of Roadways

| \# | Road name | Year | AADT |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |

A modified Z-score was used to detect outliers, and roads that did not have any consistency during years were deleted. According to Iglewicz et al. (1993), in the Modified Z-score method, median and MAD (the median of the absolute deviations) are used instead of mean and Standard deviation, and modified Z-scores defined as follows:

$$
\begin{equation*}
M_{i}=\frac{0.6745\left(x_{i}-\tilde{x}\right)}{M A D} \tag{2-1}
\end{equation*}
$$

where, $\tilde{x}$ is the median. In this study, the median refers to the median value of AADT during years (2011-2016).

MAD can be defined as follows:

$$
\begin{equation*}
M A D=\operatorname{median}\left(\left|x_{i}-\tilde{x}\right|\right) \tag{2-2}
\end{equation*}
$$

Observations will be labelled outliers when the absolute amount of $M_{i}$ is larger than $D$. Iglewicz et al. (1993) recommended 3.5 for $D$. In the following, one of the road segments is selected. Then, the steps mentioned above are performed to clarify the procedure.

For example, the tenth road segment's AADT from 2011 to 2016 is 12816, 8952, 10224, 11640, 24728, respectively. The median of this segment is 12228 , and the absolute deviations of AADTs about median are $588,3276,2004,588,22500,22740$. As a result, MAD is equal to 2640. By putting values in Eq (2-1), modified Z-scores of AADTs are $0.15,0.84,0.51,0.15$, 5.75 and 5.81. According to Iglewicz et al. (1993), AADT of 2015 and 2016 are outliers, so this segment should be removed from the sample. The results related to all road segments are in Appendix 1. (Table A.1)

### 2.1.3 Crash Data

According to Masci et al. (2015), the crash data was provided by the Regional Monitoring Center of the Piedmont Road Safety Department (CMRSS), which performs coordination functions and support, technical-operational, and documentation, which deals with collecting information in Piedmont territory on behalf of the Italian National Institute of Statistics (ISTAT). In Italy, the information framework on accidents is mainly fed from the statistics conducted by ISTAT through the investigation into the causes of death and the survey on road accidents developed in collaboration with the Italian Automobile Club (ACI). Until 2007, statistical information on accidents was collected by ISTAT through a monthly survey of all road accidents that have occurred throughout Italy that had caused at least an injury to people (i.e., fatalities and injury crashes are collected only). As a result, and according to Chapter 1, the property damage-only crashes (PDO) are not recorded.

The data was provided on an excel file which contains six years of crashes (2011-2016). The information includes the location and the type of collisions together with other relevant data. Starting from the Regional database, Turin's crashes were separated to form needed data for the task. The following steps were done to extract crash data related to each segment.

First, to present crash data on QGIS, the coordination of the location crashes was needed in the excel file. Although there were some crashes without coordination, the addresses of the nearest building to the locations where crashes happened were in the file. However, the coordination of crashes could be found by using georeferencing tools. Inside crash data
related to 2011, there were 360 crashes out of 3576 without coordination. Most of them could not be georeferenced because their addresses were not available; thus, the crashes of 2011 were excluded from the database. From 2012 to 2016, there were 159 crashes without coordinates, 80 crashes were out of Turin, and 66 crashes were inside Turin. To find coordinates of crashes without $X$ and $Y$ inside Turin, GPS Visualizer's Address Locator was used using the addresses provided in the excel file.

Second, the officers used three different coordinate reference systems to localize crashes: WGS 84 / UTM zone 32N, WGS 84, and Monte Mario (Rome) / Italy zone 1. The conversion of these reference systems to a united reference system was needed; therefore, WGS 84 / UTM zone 32Nand Monte Mario (Rome) / Italy zone 1 were converted to WGS 84. Then, the crash data of years were separated and saved in different shapefiles.

Third, in this study, the attention was on calibrating SPFs of road segments, so there was a need for a definition to distinguish segments' crashes from intersections' ones. According to HSM (2010), crashes that occur between intersections and are not related to the presence of an intersection are assigned to the roadway segment on which they occur; this includes crashes that occur within the intersection limits but are unrelated to the presence of the intersection. In this study, the braking distance of a car with $70 \mathrm{~km} / \mathrm{h}$ speed, 50 m , before and after intersections, was considered part of intersections. As a result, the crashes located outside the so-called "functional area" of the intersection were labelled as segment crashes (Figure 2-6).

The crashes of each segment were counted, and the aggregated data are in Appendix 3. (Table A.3).

Figure 2-4 Definition of functional area

### 2.1.4 Speed Data

In this study, to estimate average speed (V50) and operating speed (V85), the model proposed by Bassani et al. (2014) was used. In Bassani et al. (2014), an in-field speed survey was carried out to collect speed data from each lane of 16 different road sections. The final dataset has the following characteristics:

- vehicles in free-flow conditions; commercial vehicles were not sufficient in number to form a consistent group of observations, so data corresponding to commercial vehicles was excluded;
- cars moving at a uniform speed; any acceleration/deceleration because of traffic lights and priority signals at intersections were not considered;
- very high radiuses characterize tangent and curved segments because of the square grid pattern of the road network system of Torino; in only a few cases, there are just a few curved segments with radiuses greater than 250 , which do not cause significant speed variation on contiguous segments.

The segments with high variability in features along their length were excluded from the case study. The variables that form the database and abbreviations used in this paper are presented in Table 2-1. According to Table 2-1, some variables are numerical continuous $(\mathrm{NC})$, some are numerical discrete (ND), and some are Boolean (B).

- Dev and DevD show if there is any deviation or not and the number of deviations per km respectively (dedicated lanes for leaving or entering the primary carriageway),
- D and DD indicate if there is any driveway or not and the number of driveways per km respectively, and
- I and ID present if there is any intersection or not and the number of intersections per km , respectively, with the considered carriageway.

Simple multiple regression analysis is used by considering all the variables selected according to the BIC criterion in this model, a fixed-effect (FE) model. Then, the dependent variable is calibrated from a random effect (RE) model as follows, Taken from Bassani, 2014:

$$
\begin{equation*}
V_{r d l, i}=\beta_{0}+\sum_{k=1}^{K} \beta_{k}^{C} \cdot X_{k i}+\sum_{j=1}^{J} \beta_{j}^{D} \cdot\left(Z_{p} \cdot X_{j i}\right)+a_{r}+a_{s \mid r}+a_{l \mid s r}+\varepsilon_{r s l, i} \tag{2-3}
\end{equation*}
$$

in which $\varepsilon_{r s l}$, is the error/bias correlated with each measurement, $\beta_{0}$ is the general model intercept, $\beta_{k}^{C}$ is calibration parameter for the variables affecting the estimated mean $\left(X_{k}\right)$, and $\beta_{j}^{D}$ is calibration parameter for the variables affecting the estimated standard deviation $\left(X_{j}\right)$ respectively, and $Z_{p}$ is the standardized normal variable. By excluding the three random effects ( $a r_{r}, a_{\mathrm{s} \mid \mathrm{r}}, a_{| | \mathrm{sr}}$ ) from Eq. (2-3), the model becomes a fixed effect (FE). In Eq. (2-3), the following additional subscripts have been accepted:

- $\quad$, for the selected percentile;
- k , for the number of significant variables affecting the central tendency $\left(X_{k}\right)$, with $1 \leq \mathrm{k} \leq \mathrm{K}$, where $\mathrm{K}=24$ as presented in Table 2-1; and
- $\mathfrak{j}$, for the number of significant variables affecting the deviation from the mean $\left(X_{j}\right)$, with $1 \leq \mathrm{j} \leq \mathrm{J}$, where $\mathrm{J}=25$ (variables reported in Table 2-1 with $Z_{p}$ ).

For the calibration, each observation has been connected with the identical percentile $p\left(Z_{p}\right)$ modelled from the lane speed distribution identified by its mean and standard deviation; in particular, $Z_{j}=0$ for V50 $(p=50 \%)$, and $Z_{j}=1.036$ for V85 ( $p=85 \%$ ).

The data analysis was performed by using R-software version 3.0.2. Results were found via the Bayesian Information Criterion (BIC) application, which identifies the most significant variables from those selected as possible independent variables. Eq (2-4) is used to calculate the lowest BIC function value (fвіс).

$$
f_{B I C}=-2 \cdot \hat{L}+p \cdot \ln (n)
$$

where $\hat{L}$ is the maximized value of the log-Likelihood function, $n$ the number of observations, and $p$ is the number of parameters included in the model as follows:

$$
\begin{equation*}
p=1+K+J \tag{2-5}
\end{equation*}
$$

where the values $1, \mathrm{~K}$, and J are the size of $\beta_{0}, \beta_{k}^{C}$ and $\beta_{j}^{D}$ respectively. The independent variables that influence the minimization of the BIC function are the most significant and should be selected in the model. The results obtained from the application of the model are summarized in Table 2-4.

Table 2-4 Model coefficients and significant variables. Taken from Bassani, 2014

Before estimation of operating speed(V85) and average speed(V50) of segments by using eq (2-3), the variables of segments were found by using google satellite. Then, V85 and V50 of segments were estimated for each lane and each direction. The result will be presented in Appendix 4. (Table A.4). To evaluate the influence of lane speeds on crash occurrence, the average, max, and standard variance of V50 and V85 of lanes as covariates in models.

### 2.1.5 Other variables

The other variables of segments such as median, presence of parking line, number of access points per km, number of pedestrian crossing per km , and number of driveways per km were found using google satellite.

### 2.2 Methodology

Road safety is predicted through the number of collisions per unit of time at a roadway site. Nevertheless, the unit of time in this study is five years. To predict the crash frequency, the calibration of SPFs is a crucial step that needs some assumptions. The first assumption is related to probability (statistical) distributions of the number of collisions that follow discrete probability distributions, so Poisson distribution and Negative binomial distribution can describe crash frequency. As already said, the negative binomial distribution is an extension of the Poisson distribution and is better suited than the Poisson distribution to model crash data. The Poisson distribution is appropriate when the mean and the variance of the data are equal. There is large evidence and consensus that in crash data, the variance largely exceeds the mean. Data for which the variance exceeds the mean are overdispersed, and the negative binomial distribution is very well suited for overdispersed data.

A regression model is needed to calibrate SPFs and the relationship between independent and dependent variables of interest, i.e., the crash frequency. The best choice is to use Generalized Linear Modelling (GLM) because of the discrete nature of crash frequency. The next step is the validation process of regression model development. In the following section, the content mentioned above will be thoroughly discussed.

### 2.2.1 Generalized Linear Model (GLM)

According to SAS/STAT® 13.1 User's Guide (2013), the form of the traditional linear model is:

$$
\begin{equation*}
y_{i}=x_{i} \beta+\varepsilon_{i} \tag{2-6}
\end{equation*}
$$

where $y_{i}$ is the ith observation's response variable. The quantity $x_{i}$ is a fixed, or nonrandom, column vector of covariates, or explanatory variables, for observation $i$ that is known from the experimental environment $\beta$. The least squares fit the data $y$ is used to estimate the vector of unknown coefficients. The $\varepsilon_{i}$ are random variables that are supposed to be independent and normal, which are called residuals. The predicted value of $y_{i}$, denoted by $m$, is:

$$
\begin{equation*}
m=x_{i} \beta \tag{2-7}
\end{equation*}
$$

Traditional linear models are widely employed in statistical data analysis, although they are not ideal for some problems, such as those listed below.

- For instance, when modelling counts or measured proportions that are regarded discrete, the normal distribution (which is continuous) may not be suitable.
- The traditional linear model may not be appropriate if the data's mean is naturally constrained to a range of values because the linear predictor $x_{i} \beta$ can take any value. The mean of a measured proportion, for example, is between 0 and 1 but in a standard linear model, the linear predictor of the mean is not constrained to this range.
- It is possible that assuming that the variance of the data is constant across all observations is unrealistic. It is not uncommon, for example, to see data where the variance increase as the data's mean increases.

A generalized linear model is an extension of the traditional linear model that can be used to solve a broader range of data analysis problems. The following are the components of a generalized linear model:

- the linear component is as same as traditional linear models:

$$
\begin{equation*}
\eta_{i}=x_{i} \beta \tag{2-8}
\end{equation*}
$$

- The relationship between the expected value of $y_{i}$ and the linear predictor $\eta_{i}$ is monotonic differentiable link function g :

$$
\begin{equation*}
g(m)=x_{i} \beta \tag{2-9}
\end{equation*}
$$

- the response variables $y_{i}$ are independent for $i=1,2, \ldots$ and its probability distribution is an exponential distribution, which means that the variance of the response depends on the mean $m$ via a variance function V :

$$
\begin{equation*}
\operatorname{Var}\left(y_{i}\right)=\frac{V(m)}{\varphi \omega_{i}} \tag{2-10}
\end{equation*}
$$

where $\varphi$ is an overdispersion parameter and $\omega_{i}$ is a known weight for each observation. The dispersion parameter $\left(\frac{1}{\varphi}\right)$ is equal to one for binomial or Poisson distribution or must be estimated.

### 2.2.2 Negative Binomial Distribution

According to Washington et al. (2011), in Poisson distribution, the mean and variance are equal $(E[y i]=\operatorname{VAR}[y i])$. If they are not equal, the data are under dispersed $(E[y i]>\operatorname{VAR}[y i])$ or overdispersed $(E[y i]<\operatorname{VAR}[y i])$. Overdispersion can happen because of a variety of reasons, which depend on the phenomenon under investigation. In many investigations, the main reason is that variables influencing the Poisson rate across observations have been eliminated from the regression.

After rewriting Poisson's equation, the negative binomial model is derived as follow, for each observation i:

$$
\begin{equation*}
E[m]=E X P(\beta x i+\varepsilon i) \tag{2-11}
\end{equation*}
$$

where $\operatorname{EXP}(\varepsilon i)$ is a disturbance term of Gamma-distributed with mean one and variance $1 / \varphi$. The additional part allows the variance to be different from the mean, as follow:

$$
\begin{equation*}
\operatorname{VAR}\left[y_{i}\right]=E[m]+\operatorname{VAR}[m]=E\left[y_{i}\right]\left[1+\frac{1}{\varphi} E\left[y_{i}\right]\right]=\bar{y}+\frac{1}{\varphi} \bar{y}^{2} \tag{2-12}
\end{equation*}
$$

where, $E[m]$ and $\operatorname{VAR}[m]$ are the mean and the variance $m$ 's of units the population, respectively. While $\overline{\mathrm{y}}=E\left[y_{i}\right]$ is the mean number of observed crashes per unit of time. The parameter $\varphi$ is the overdispersion parameter. The negative binomial distribution is as follow:

$$
\begin{equation*}
P\left(y_{i}\right)=\frac{\Gamma\left(y_{i}+b\right)}{\Gamma(b) y_{i}!}\left(\frac{a}{a+1}\right)^{b}\left(\frac{1}{a+y_{i}}\right)^{y_{i}} \tag{2-13}
\end{equation*}
$$

where $a$ and $b$ are parameters of gamma distribution which are:

$$
\begin{align*}
& a=\frac{E[m]}{\operatorname{Var}[m]}  \tag{2-14}\\
& b=\frac{E[m]^{2}}{\operatorname{Var}[m]} \tag{2-15}
\end{align*}
$$

and $\Gamma(\cdot)$ is a gamma function which results in the likelihood function:

$$
\begin{equation*}
L(m)=\prod_{i} \frac{\Gamma\left(y_{i}+b\right)}{\Gamma(b) y_{i}!}\left(\frac{a}{a+1}\right)^{b}\left(\frac{1}{a+y_{i}}\right)^{y_{i}} \tag{2-16}
\end{equation*}
$$

According to HSM 2010, as the overdispersion parameter value increases, more emphasis is placed on the observed rather than the predicted crash frequency. When the data used to develop a model are greatly dispersed, the reliability of the resulting predicted crash frequency is likely to be lower. On the other hand, when the data used to develop a model have little overdispersion, the reliability of the resulting SPF is likely to be higher.

### 2.2.3 Goodness of Fit

According to SAS/STAT® 13.1 User's Guide (2013), two statistics to assess the goodness of fit of a given generalized linear model are the scaled deviance and Pearson's chi-square statistic. When the dispersion parameter $(1 / \varphi)$ is a fixed value, the scaled deviance is twice the difference between the maximum achievable log-likelihood and the log-likelihood at the maximum likelihood estimates of the regression parameters.

Where $l(y, m)$ is the log-likelihood function represented as a function of the predicted mean values $(m)$ and the vector $(y)$ of response values, the scaled deviance is:

$$
\begin{equation*}
D^{*}(y, m)=2(l(y, y)-l(y, m)) \tag{2-17}
\end{equation*}
$$

The deviance for the Negative binomial probability distributions is:

$$
\begin{equation*}
\text { Negetive Binomial } \quad 2 \sum_{i}\left[y \log (y / m)-\left(y+\varphi \omega_{i}\right) \log \left(\frac{y+\varphi \omega_{i}}{m+\varphi \omega_{i}}\right)\right] \tag{2-18}
\end{equation*}
$$

Pearson's chi-square statistic is defined as:

$$
\begin{equation*}
X^{2}=\sum_{i} \frac{\omega_{i}\left(y_{i}-m\right)^{2}}{V[m]} \tag{2-19}
\end{equation*}
$$

and the scaled Pearson's chi-square is $X^{2} / \varphi$. Both the scaled deviance and the Pearson $X^{2}$-statistic are asymptotically $X^{2}$-distributed with $n-p$ degrees of freedom when $p$ denotes the number of model parameters and $n$ number of observations (Aitkin et al., 1989). For a well-fitted SPF, scaled deviance (SD) and Pearson's chi-square values should be approximately equal to the degree of freedom (DF).

Under the particular condition, the scaled deviance and the scaled Pearson's chi-square have a limiting chi-square distribution, with degrees of freedom equal to the difference between the number of observations and the number of estimated model parameters. Thus, the scaled version is helpful as an approximate guide for the goodness of fit of a given model.

### 2.2.4 Other Fit Statistics

According to Mehta et al. (2013), A statistical model's goodness of fit refers to how well it matches the data. Goodness-of-fit approaches, on the other hand, have been used to develop an optimal crash prediction model and select the models that best fit the data. Furthermore, when too many parameters are included in the regression model, goodness-of-fit methods aid in lowering the risk of SPF overfitting can occur (Srinivasan et al., 2013). The Akaike Information Criterion (AIC), Akaike Information Criterion corrected (AICC), and the Bayesian Information Criterion (BIC) were employed in this study to examine the goodness-of-fit and overfitting of the developed models. In the following subsections, these good-offit measurements are further explained.

### 2.2.4.1 Akaike Information Criterion (AIC)

The AIC is a numerical assessment of the model's consistency for the data collected. AIC, on the other hand, is a model selection criterion that evaluates a model's goodness-of-fit. The AIC is represented by the following equation taken from Khan et al. (2013).

$$
\begin{equation*}
A I C=2 p-2 \ln (L) \tag{2-20}
\end{equation*}
$$

where p is the number of parameters in the model, and L is the maximized log-likelihood for the model.

### 2.2.4.2 Akaike information criterion corrected (AICC)

The Akaike information criterion corrected (AICC) value is proportional to the sample size; the lower the AICC value, the better the model. When choosing a model based on AICC, increasing sample size generates an increasing trend to accept the more complex model (Garber et al., 2001). The model's AICC value can be calculated using the equation below taken from Dissanayake et al. (2016).

$$
\begin{equation*}
A I C C=2 p-2 \ln (L)+\frac{2 p(p+1)}{n-p-1} \tag{2-21}
\end{equation*}
$$

where n is the number of model observations.

### 2.2.4.3 Bayesian information criterion (BIC)

A related metric is the Bayesian information criterion (BIC), which is defined by:

$$
\begin{equation*}
B I C=-2 \operatorname{Ln}(L)+p \operatorname{Ln}(n) \tag{2-22}
\end{equation*}
$$

### 2.2.5 Safety Performance Function

An SPF is a regression model used in road safety to estimate the $E[m]$, i.e., the predicted number of collisions per unit of time for different facility types such as intersections and road segments. The independent variables of the regression model are usually roadway and traffic features. The SPF form for road segments, which is used in this study, is the following:

$$
\begin{equation*}
E(m)=e^{a_{0}} \cdot A A D T^{a_{1}} \cdot L^{a_{2}} \cdot \exp ^{\sum b_{j} \cdot x_{j}} \tag{2-23}
\end{equation*}
$$

The linearized form of SPF is the following:

$$
\begin{equation*}
\ln (E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+\sum b_{j} \cdot x_{j} \tag{2-24}
\end{equation*}
$$

where $E(m)$ predicted number of collisions per unit of time; $a_{0}, a_{1}, a_{2}$ and $b_{j}$ are the regression parameters; L is the length of the segment; AADT is the Average Annual Daily Traffic; and $x_{j}$ are a further variable. In this study, SAS studio software was used to calibrate Safety Performance functions.

## Chapter 3

## 3 Results and Discussion

The development of SPFs was carried out in two steps. First, SPFs were estimated on 83 segments, and then segments were increased to 105 , and the new SPFs were calibrated on them. In each step, two groups of SPFs were developed; the first group is related to speed variables, and the second group is related to geometric variables. Before discussing the results of calibration of SPFs, the variables used in the calibration of SPFs will be introduced in the following table:

Table 3-1 List of variables

| $\#$ | Variable | Symbol | Unit | min. | max. | mean | SD |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | Average annual daily traffic | AADT | - | 8744 | 36880 | 17757.23 | 5201.84 |
| 2 | Length of segments | L | km | 0.04 | 1.10 | 0.29 | 0.16 |
| 3 | Average of the operating speed of lanes | V 85 | $\mathrm{~km} / \mathrm{h}$ | 24.08 | 136.72 | 83.66 | 26.64 |
| 4 | Average of the average speed of lanes | V 50 | $\mathrm{~km} / \mathrm{h}$ | 13.56 | 126.31 | 74.53 | 26.70 |
| 5 | Maximum of the operating speed of lanes | V 85 Max | $\mathrm{km} / \mathrm{h}$ | 27.74 | 140.38 | 86.72 | 25.89 |
| 6 | Maximum of the average speed of lanes | $\mathrm{V} 50 \mathrm{Max}:$ | $\mathrm{km} / \mathrm{h}$ | 16.66 | 129.41 | 77.13 | 26.09 |
| 7 | The standard deviation of the operating | V 85 SD | $\mathrm{km} / \mathrm{h}$ |  |  |  |  |
|  | $\quad$ speed of lanes |  |  |  | 7.33 | 3.95 | 2.56 |
| 8 | The standard deviation of the average | V 50 SD | $\mathrm{km} / \mathrm{h}$ |  |  |  |  |
| 9 | $\quad$ speed of lanes |  |  | 0 | 6.20 | 3.36 | 2.17 |
| 10 | $\quad$ Median | Parking line | - | 0 | 1 | - | - |
| 11 | Number of access points per km | PL | ACD | $\mathrm{No} / \mathrm{km}$ | 0 | 14.32 | 4.03 |
| 12 | Number of pedestrian crossing per km | PCD | $\mathrm{No} / \mathrm{km}$ | 0 | 26.49 | 1.06 | 2.98 |
| 13 | Number of driveways per km | DD | $\mathrm{No} / \mathrm{km}$ | 0 | 92.72 | 16.13 | 16.18 |

${ }^{*}$ M shows the presence of median ( $1=$ presence of median, $0=$ Otherwise)
**PL shows the presence of parking line ( $1=$ presence of parking line, $0=$ Otherwise)

### 3.1 The Frist Step

In this step, 116 road segments were selected for calibration of SPFs, and after deleting AADT outliers, 83 segments remained to calibrate SPFs.

### 3.1.1 Speed-based SPFs

Before starting calibration of SPFs, in order to consider speed as an independent variable, two different approaches were tested. In the first approach, the natural logarithm of speed was regarded as a variable. In the second approach, speed was assumed to have a linear function with a natural logarithm of the crash frequency. For testing, V50 (average speed) was used. The results are as follow:

- First approach:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot \ln (V 50) \tag{3-1}
\end{equation*}
$$

Where, $E(m)$ is predicted crash frequency in 5 years.
Table 3-2 Summary of results of estimation for the first approach
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate | Standard <br> Error | Wald 95\% <br> Confidence <br> Limits | Wald Chi- <br> Square | Pr > ChiSq |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Intercept | 1 | $a_{0}$ | -6.0004 | 3.9379 | -13.7186 | 1.7178 | 2.32 |

- Second approach:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=\mathrm{a}_{0}+\mathrm{a}_{1} \cdot \ln (\text { AADT })+\mathrm{a}_{2} \cdot \ln (\mathrm{~L})+\mathrm{b}_{1} \cdot \mathrm{~V} 50 \tag{3-2}
\end{equation*}
$$

Table 3-3 Summary of results of estimation for the second approach
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard Error |  | Wald 95\% Confidence Limits |  | Wald ChiSquare | Pr $>$ ChiSq |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Intercept | 1 | $a_{0}$ | -6.2668 | 3.7524 |  | -13.6214 | 1.0877 | 2.79 | 0.0949 |
| $\ln (\mathrm{AADT})$ | 1 | $a_{1}$ | 1.0456 | 0.3824 |  | 0.2961 | 1.7951 | 7.48 | 0.0063 |
| $\ln (\mathrm{L})$ | 1 | $a_{2}$ | 1.9037 | 0.2492 |  | 1.4153 | 2.3921 | 58.37 | <. 0001 |
| V50 | 1 | $b_{1}$ | -0.0066 | 0.0043 |  | -0.0151 | 0.0019 | 2.30 | 0.1292 |
| Dispersion | 1 | $1 / \varphi$ | 0.4980 | 0.1392 |  | 0.2880 | 0.8613 |  |  |
| Criteria For Assessing Goodness of Fit |  |  |  |  |  |  |  |  |  |
|  | Criterion |  |  |  | DF |  | Value |  | Value/DF |
|  | Deviance |  |  |  | 79 |  | 88.0030 |  | 1.1140 |
|  | Scaled Deviance |  |  |  | 79 |  | 88.0030 |  | 1.1140 |
|  | Pearson Chi-Square |  |  |  | 79 |  | 76.3643 |  | 0.9666 |
|  | Scaled Pearson X2 |  |  |  | 79 |  | 76.3643 |  | 0.9666 |
|  | Log Likelihood |  |  |  |  |  | 251.4982 |  |  |
|  | Full Log Likelihood |  |  |  |  |  | -176.6911 |  |  |
|  | AIC (smaller is better) |  |  |  |  |  | 363.3821 |  |  |
|  | AICC (smaller is better) |  |  |  |  |  | 364.1613 |  |  |
|  | BIC (smaller is better) |  |  |  |  |  | 375.4763 |  |  |

The Scaled Deviance (SD) and Pearson chi-square statistic, AIC, AICC, and BIC were used to assess the goodness of fit of the models. The SD and Pearson $X^{2}$-statistics of the first and second models are $87.47,75.13,88.00$, and 76.36 , respectively. By considering, the degree of freedom is equal to 79; the first approach is better than the second one. While the first model's AIC, AICC, and BIC values are smaller than the first one, the second approach is a better approach by considering overfitting parameters. In addition, at the $5 \%$ level of significance, the second model has provided a good fit to the current data set. Considering all analyses together, the second model is better than the first one; therefore, the next SPFs will be developed based on the second model.

### 3.1.1.1 SPF (1 ${ }^{\text {st }}$ trail)

In this SPF, length, AADT, and average V50 of lanes are considered independent variables, and the results are represented in the following table.

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 50 \tag{3-3}
\end{equation*}
$$

Table 3-4 Summary of results of estimation for SPF (1 ${ }^{\text {st }}$ trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard Error |  | Wald 95\% Confidence Limits |  | Wald ChiSquare | Pr $>$ ChiSq |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Intercept | 1 | $a_{0}$ | -6.2668 | 3.7524 |  | -13.6214 | 1.0877 | 2.79 | 0.0949 |
| $\ln (\mathrm{AADT})$ | 1 | $a_{1}$ | 1.0456 | 0.3824 |  | 0.2961 | 1.7951 | 7.48 | 0.0063 |
| $\ln (\mathrm{L})$ | 1 | $a_{2}$ | 1.9037 | 0.2492 |  | 1.4153 | 2.3921 | 58.37 | <. 0001 |
| V50 | 1 | $b_{1}$ | -0.0066 | 0.0043 |  | -0.0151 | 0.0019 | 2.30 | 0.1292 |
| Dispersion | 1 | $1 / \varphi$ | 0.4980 | 0.1392 |  | 0.2880 | 0.8613 |  |  |
| Criteria For Assessing Goodness of Fit |  |  |  |  |  |  |  |  |  |
|  | Criterion |  |  |  | DF |  | Value |  | Value/DF |
|  | Deviance |  |  |  | 79 |  | 88.0030 |  | 1.1140 |
|  | Scaled Deviance |  |  |  | 79 |  | 88.0030 |  | 1.1140 |
|  | Pearson Chi-Square |  |  |  | 79 |  | 76.3643 |  | 0.9666 |
|  | Scaled Pearson X2 |  |  |  | 79 |  | 76.3643 |  | 0.9666 |
|  | Log Likelihood |  |  |  |  |  | 251.4982 |  |  |
|  | Full Log Likelihood |  |  |  |  |  | -176.6911 |  |  |
|  | AIC (smaller is better) |  |  |  |  |  | 363.3821 |  |  |
|  | AICC (smaller is better) |  |  |  |  |  | 364.1613 |  |  |
|  | BIC (smaller is better) |  |  |  |  |  | 375.4763 |  |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the 5\% level of significance, the intercept and $V 50$ are not significant. The estimate $b_{1}$ in Table 3-4 is negative, indicating that the predicted crash frequency decreases with speed, which is not reasonable because, by increasing speed, the probability of a crash occurring should increase. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 88.00 , and 76.36 respectively, and the degrees of freedom is 79 indicating that the model is well fitted.
Operating speed is the threshold between aggressive and less aggressive drivers, which can influence the crash occurrence, so the next model is based on V85 (average operating speed of lanes) will be used instead of V50.

### 3.1.1.2 $\operatorname{SPF}\left(2^{\text {nd }}\right.$ trail $)$

In this SPF, length, AADT, and average V85 are considered as independent variables, and the results follow:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 85 \tag{3-4}
\end{equation*}
$$

Table 3-5 Summary of results of estimation for SPF (2 ${ }^{\text {nd }}$ trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence <br> Limits | Wald Chi- <br> Square | Pr $>$ ChiSq |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Intercept | 1 | $a_{0}$ | -6.2050 | 3.7529 | -13.5606 | 1.1506 | 2.73 | 0.0983 |
| $\ln (\mathrm{AADT})$ | 1 | $a_{1}$ | 1.0480 | 0.3819 | 0.2995 | 1.7965 | 7.53 | 0.0061 |
| $\ln (\mathrm{~L})$ | 1 | $a_{2}$ | 1.9076 | 0.2492 | 1.4192 | 2.3961 | 58.59 | $<.0001$ |
| V85 | 1 | $b_{1}$ | -0.0068 | 0.0044 | -0.0155 | 0.0018 | 2.43 | 0.1191 |
| Dispersion | 1 | $1 / \varphi$ | 0.4962 | 0.1389 | 0.2867 | 0.8590 |  |  |

Criteria For Assessing Goodness of Fit

| Criterion | DF | Value | Value/DF |
| :---: | :---: | :---: | :---: |
| Deviance | 79 | 88.0323 | 1.1143 |
| Scaled Deviance | 79 | 88.0323 | 1.1143 |
| Pearson Chi-Square | 79 | 76.4488 | 0.9677 |
| Scaled Pearson X2 | 79 | 76.4488 | 0.9677 |
| Log Likelihood |  | 251.5571 |  |
| Full Log Likelihood | -176.6322 |  |  |
| AIC (smaller is better) | 363.2644 |  |  |
| AICC (smaller is better) |  | 364.0436 |  |
| BIC (smaller is better) |  | 375.3586 |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the $5 \%$ level of significance, the intercept and $V 85$ are not significant. The estimate $b_{1}$ in Table 3-5 is negative, indicating that the predicted crash frequency decreases with speed. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 88.03 , and 76.44 respectively, and the degrees of freedom is 79 indicating that the model is well fitted.
Based on the background section, in some studies, the SPFs were calibrated by considering average and standard deviation of speed as a variable, so the two following SPFs are calibrated based on average speeds of lanes and standard deviation.

### 3.1.1.3 SPF (3 ${ }^{\text {rd }}$ trail)

In this SPF, length, AADT, V50, and V50SD are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 50+b_{2} \cdot V 50 S D \tag{3-5}
\end{equation*}
$$

Table 3-6 Summary of results of estimation for SPF (3 ${ }^{\text {rd }}$ trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard Error | Wald 95\% Confidence Limits |  | Wald ChiSquare | Pr $>$ ChiSq |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Intercept | 1 | $a_{0}$ | -7.0013 | 3.5886 | -14.0348 | 0.0322 | 3.81 | 0.0511 |
| $\ln (\mathrm{AADT})$ | 1 | $a_{1}$ | 1.1914 | 0.3698 | 0.4667 | 1.9161 | 10.38 | 0.0013 |
| $\ln (\mathrm{L})$ | 1 | $a_{2}$ | 1.8118 | 0.2385 | 1.3444 | 2.2792 | 57.72 | <. 0001 |

| AIC (smaller is better) |  |  |  |  |  | 357.1515 |  |  |
| AICC (smaller is better) |  |  |  |  |  | 358.2568 |  |  |
| BIC (smaller is better) |  |  |  |  |  | 371.6646 |  |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, the intercept is not significant at the $5 \%$ level of significance. The estimate $b_{1}$ and $b_{2}$ in Table 3-6 are negative significant, indicating that the predicted crash frequency decreases with speed, which is not reasonable because, by increasing speed, the probability of a crash occurring should increase, so the sign of $b_{1}$ should be positive. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 86.81, and 78.75 respectively, and the degrees of freedom is 78 indicating that the model is well fitted.

### 3.1.1.4 SPF (4th trail)

In this SPF, length, AADT, average V85 of lanes, and standard deviation of V85 are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 85+b_{2} \cdot V 85 S D \tag{3-6}
\end{equation*}
$$

Table 3-7 Summary of results of estimation for SPF (4th trail)

Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence Limits | Wald Chi- <br> Square | Pr > ChiSq |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Intercept | 1 | $a_{0}$ | -6.9129 | 3.5897 | -13.9486 | 0.1228 | 3.71 | 0.0541 |
| $\ln (\mathrm{AADT})$ | 1 | $a_{1}$ | 1.1945 | 0.3696 | 0.4700 | 1.9190 | 10.44 | 0.0012 |

| V85 | 1 | $b_{1}$ | -0.0114 | 0.0044 | -0.0200 | -0.0027 | 6.64 | 0.0100 |
| V85SD | 1 | $b_{2}$ | -0.1274 | 0.0444 | -0.2145 | -0.0403 | 8.21 | 0.0042 |
| Dispersion | 1 | $1 / \varphi$ | 0.4173 | 0.1227 | 0.2345 | 0.7424 |  |  |

Criteria For Assessing Goodness of Fit

| Criterion | DF | Value | Value/DF |
| :---: | :---: | :---: | :---: |
| Deviance | 78 | 86.9483 | 1.1147 |
| Scaled Deviance | 78 | 86.9483 | 1.1147 |
| Pearson Chi-Square | 78 | 79.7828 | 1.0229 |
| Scaled Pearson X2 | 78 | 79.7828 | 1.0229 |
| Log Likelihood |  | 255.5841 |  |
| Full Log Likelihood | -172.6052 |  |  |
| AIC (smaller is better) |  | 357.2104 |  |
| AICC (smaller is better) |  | 358.3156 |  |
| BIC (smaller is better) |  | 371.7234 |  |

[^0]According to the above table, at the $5 \%$ level of significance, the intercept is not significant. The estimate $b_{1}$ and $b_{2}$ in Table 3-7 are negative significant, indicating that the predicted crash frequency decreases with speed. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 86.94 , and 79.78 respectively, and the degrees of freedom is 78 indicating that the model is well fitted.

According to the European Commission website (2021), More recent studies, mainly conducted in Australia and Great Britain, also found that higher accident risk is related to
faster drivers. As a result, the SPFs are calibrated by considering the maximum speed of lanes in the two subsequent trials.

### 3.1.1.5 SPF ( $5^{\text {th }}$ trail )

In this SPF, length, AADT, and V50Max are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 50 \max \tag{3-7}
\end{equation*}
$$

Table 3-8 Summary of results of estimation for SPF (5 th trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence <br> Limits | Wald Chi- <br> Square | Pr > ChiSq |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

[^1]According to the above table, at the $5 \%$ level of significance, the intercept and $V 50 \mathrm{max}$ are not significant. The estimate $b_{1}$ in Table 3-8 is negative, indicating that the predicted crash frequency decreases with speed, which is not reasonable. Also, the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 88.23, and 76.95 respectively, and the degrees of freedom is 79 indicating that the model is well fitted.

### 3.1.1.6 SPF (6 ${ }^{\text {th }}$ trail )

In this SPF, length, AADT, and V85Max are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 85 \max \tag{3-8}
\end{equation*}
$$

Table 3-9 Summary of results of estimation for SPF ( $6^{\text {th }}$ trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard Error | Wald 95\% Confidence Limits |  | Wald ChiSquare | Pr > ChiSq |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Intercept | 1 | $a_{0}$ | -6.0592 | 3.7218 | -13.3538 | 1.2353 | 2.65 | 0.1035 |
| $\ln$ (AADT) | 1 | $a_{1}$ | 1.0462 | 0.3788 | 0.3038 | 1.7885 | 7.63 | 0.0057 |
| $\ln (\mathrm{L})$ | 1 | $a_{2}$ | 1.9079 | 0.2464 | 1.4250 | 2.3909 | 59.95 | <. 0001 |
| V85max | 1 | $b_{1}$ | -0.0082 | 0.0045 | -0.0170 | 0.0006 | 3.32 | 0.0683 |
| Dispersion | 1 | $1 / \varphi$ | 0.4832 | 0.1372 | 0.2770 | 0.8428 |  |  |
| Criteria For Assessing Goodness of Fit |  |  |  |  |  |  |  |  |
| Criterion |  |  |  | DF |  | Value |  | Value/DF |
| Deviance |  |  |  | 79 |  | 88.3072 |  | 1.1178 |
| Scaled Deviance |  |  |  | 79 |  | 88.3072 |  | 1.1178 |
| Pearson Chi-Square |  |  |  | 79 |  | 77.2100 |  | 0.9773 |
| Scaled Pearson X2 |  |  |  | 79 |  | 77.2100 |  | 0.9773 |
| Log Likelihood |  |  |  |  |  | 251.9735 |  |  |
| Full Log Likelihood |  |  |  |  |  | -176.2158 |  |  |
| AIC (smaller is better) |  |  |  |  |  | 362.4316 |  |  |
| AICC (smaller is better) |  |  |  |  |  | 363.2108 |  |  |
| BIC (smaller is better) |  |  |  |  |  | 374.5258 |  |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the $5 \%$ level of significance, the intercept and $V 85 \mathrm{max}$ are not significant. The estimate $b_{1}$ in Table 3-9 is negative, indicating that the predicted crash frequency decreases with speed. Also, the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 88.31, and 77.21 respectively, and the degrees of freedom is 79 indicating that the model is well fitted.

In the two successive trials, the SPFs are calibrated by considering the maximum speed of lanes, the average speed of lanes, and standard deviation of speed as variables to estimate how they are influential in a crash occurring.

### 3.1.1.7 $\operatorname{SPF}\left(7^{\text {th }}\right.$ trail $)$

In this SPF, length, AADT, average V50, V50SD, V50max are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 50+b_{2} \cdot V 50 S D+b_{3} \cdot V 50 \max \tag{3-9}
\end{equation*}
$$

Table 3-10 Summary of results of estimation SPF (7 th trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard Error | Wal <br> Confiden | $\begin{aligned} & \text { 95\% } \\ & \text { ce Limits } \end{aligned}$ | Wald ChiSquare | Pr $>$ ChiSq |

| Pearson Chi-Square |  |  |  | 77 |  | 80.2990 |  | 1.0428 |
| Scaled Pearson X2 |  |  |  | 77 |  | 80.2990 |  | 1.0428 |
| Log Likelihood |  |  |  |  |  | 257.5575 |  |  |
| Full Log Likelihood |  |  |  |  |  | -170.6318 |  |  |
| AIC (smaller is better) |  |  |  |  |  | 355.2635 |  |  |
| AICC (smaller is better) |  |  |  |  |  | 356.7569 |  |  |
| BIC (smaller is better) |  |  |  |  |  | 372.1954 |  |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the $5 \%$ level of significance, the intercept, $V 50$, and $V 50 S D$ are not significant. The estimate $b_{1}$ and $b_{2}$ in Table 3-10 are positive, indicating that the predicted crash frequency increases with increasing speed. While V50max is significant and the estimate $b_{3}$ in Table 3-10 is negative. Also, the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 89.01 , and 80.30 respectively, and the degrees of freedom is 77 indicating that the model compared to previous models is not well fitted.

### 3.1.1.8 $\operatorname{SPF}\left(8^{\text {th }}\right.$ trail $)$

In this SPF, length, AADT, average V85 of lanes, the standard deviation of V85, and maximum V85 of lanes are considered as independent variables, and the results are the following:
$\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 85+b_{2} \cdot V 85 S D+b_{3} \cdot V 85 \max$
Table 3-11 Summary of results of estimation for SPF (8 $8^{\text {th }}$ trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence Limits | Wald Chi- <br> Square | Pr > ChiSq |  |
| :---: | :---: | :---: | :---: | :---: | :--- | :---: | :---: | :---: |

| BIC (smaller is better) |  | 371.9095 |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the $5 \%$ level of significance, the intercept and $V 85 S D$ are not significant. The estimate $b_{1}$ and $b_{2}$ in Table 3-11 are positive, indicating that the predicted crash frequency increases with increasing speed. While V50max is significant and the estimate $b_{3}$ is negative. Also, the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 89.15 , and 80.57 respectively, and the degrees of freedom is 77 indicating that the model compared to previous models is not well fitted.

### 3.1.2 Geometric features SPFs

For calibration of the second group of SPFs, a different methodology was followed. The method is based on Greibe (2001). In this study, all variables were included in the first model for the regression analysis, and insignificant variables were excluded one by one, starting with the least significant variables for the following models. The result will be presented in the following sections.

### 3.1.2.1 SPF ( $9^{\text {th }}$ trail )

For calibration of this SPF, AADT, Length, M, PL, ACD, PCD, and DD were used, and the result is as follow:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot M+b_{2} \cdot P L+b_{3} \cdot A C D+b_{4} \cdot P C D+b_{5} . \tag{3-11}
\end{equation*}
$$

Table 3-12 Summary of results of estimation for SPF (9th trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence <br> Limits | Wald Chi- <br> Square | Pr > ChiSq |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Criteria For Assessing Goodness of Fit

| Criterion | DF | Value | Value/DF |
| :---: | :---: | :---: | :---: |
| Deviance | 75 | 87.8811 | 1.1717 |
| Scaled Deviance | 75 | 87.8811 | 1.1717 |
| Pearson Chi-Square | 75 | 72.4174 | 0.9656 |
| Scaled Pearson X2 | 75 | 72.4174 | 0.9656 |
| Log Likelihood |  | 268.9371 |  |
| Full Log Likelihood | -159.2522 |  |  |
| AIC (smaller is better) |  | 336.5044 |  |
| AICC (smaller is better) |  | 338.9701 |  |
| BIC (smaller is better) |  | 358.2739 |  |

[^2]According to Table 3-12, at the 5\% level of significance, significance $M, P L$, and $P C D$ are not significant. The estimate $b_{1}$ is negative, indicating that the predicted crashes decrease with the median presence. While the estimate $b_{2}$ is positive, which shows that the presence of a parking line increases the probability of the crash occurrence. Nevertheless, the estimate $b_{3}$, $b_{4}$ and $b_{5}$ are positive, indicating that the predicted crashes increase by increasing pedestrian crossing, driveway, access points of road segments. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance, and the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 87.88 , and 72,41 respectively, and the degrees of freedom is 75 indicating that the model is somehow well fitted.

According to Table 3-12, the lowest significance level is related to the median, so It will be deleted in the next SPFs.

### 3.1.2.2 $\operatorname{SPF}\left(10^{\text {th }}\right.$ trail $)$

For calibration of this SPF, AADT, length, PL, ACD, PCD, and DD were used, and the result follows:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot A C D+b_{2} \cdot P C D+b_{3} \cdot P L+b_{4} \cdot D D \tag{3-12}
\end{equation*}
$$

According to Table 3-13, at the 5\% level of significance, $P L$ and $P C D$ are not significant. The estimate $b_{2}$ and $b_{3}$ are positive, showing that parking line and pedestrian crossing density increase the probability of crash occurrence. Nevertheless, the estimate $b_{1}$ and $b_{4}$ are positive and significant at the $5 \%$ level of significance, indicating that the predicted crashes increase by the increasing driveway and access points of the road segments. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance, and the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$ Statistics models are 88.10 and 72.55, respectively, and the degrees of freedom are 76, indicating that the model is somehow well fitted.

According to Table 3-13, the lowest significance level is related to PL, so It will be deleted in the next SPFs.

Table 3-13 Summary of results of estimation for SPF (10 th rail)

| Analysis Of Maximum Likelihood Parameter Estimates |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

### 3.1.2.3 $\operatorname{SPF}\left(11^{\text {th }}\right.$ trail $)$

For calibration of this SPF, AADT, length, ACD, PCD, and DD were used, and the result is as follow:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot A C D+b_{2} \cdot P C D+b_{3} \cdot D D \tag{3-13}
\end{equation*}
$$

Table 3-14 Summary of results of estimation for SPF (11 ${ }^{\text {th }}$ trail)

| Analysis Of Maximum Likelihood Parameter Estimates |  |  |  |  |  |  |  |  |

| Full Log Likelihood |  |  |  |  | -159.5521 |  |  |  |
| AIC (smaller is better) |  |  |  |  | 333.1042 |  |  |  |
| AICC (smaller is better) |  |  |  |  | 334.5975 |  |  |  |
| BIC (smaller is better) |  |  |  |  | 350.0361 |  |  |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the table, at the $5 \%$ level of significance, $P C D$ is not significant, and the estimate $b_{2}$ is positive, which shows pedestrian crossing density is increasing the probability of crash occurrence. Nevertheless, the estimate $b_{1}$ and $b_{3}$ are positive and significant at the $5 \%$ level of significance, indicating that the predicted crashes increase by the increasing driveway and access points of the road segments. Also, and the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-Statistic models are 87.86 , and 72,41 respectively, and the degrees of freedom is 77, indicating that the model is somehow well fitted. Among variables, the PCD is not significant, so that it would be deleted in the next SPFs.

### 3.1.2.4 SPF (12 ${ }^{\text {th }}$ trail $)$

For calibration of this SPF, AADT, length, ACD and DD were used, and the result is as follow:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot A C D+b_{2} \cdot D D \tag{3-14}
\end{equation*}
$$

Table 3-15 Summary of results of estimation for SPF (12 ${ }^{\text {th }}$ trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence Limits | Wald Chi- <br> Square | Pr $>$ ChiSq |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Intercept | 1 | $a_{0}$ | -9.8015 | 3.1167 | -15.9100 | -3.693 | 9.89 | 0.0017 |
| $\ln (\mathrm{AADT})$ | 1 | $a_{1}$ | 1.2150 | 0.3167 | 0.5943 | 1.8357 | 14.72 | 0.0001 |
| $\ln (\mathrm{~L})$ | 1 | $a_{2}$ | 1.5122 | 0.1867 | 1.1463 | 1.8781 | 65.60 | $<.0001$ |
| ACD | 1 | $b_{1}$ | 0.1173 | 0.0203 | 0.0775 | 0.1570 | 33.37 | $<.0001$ |
| DD | 1 | $b_{2}$ | 0.0178 | 0.0060 | 0.0059 | 0.0296 | 8.64 | 0.0033 |
| Dispersion | 1 | $1 / \varphi$ | 0.1879 | 0.0778 | 0.0834 | 0.4231 |  |  |

Criteria For Assessing Goodness of Fit

| Criterion | DF | Value | Value/DF |
| :---: | :---: | :---: | :---: |
| Deviance | 78 | 87.7469 | 1.1250 |
| Scaled Deviance | 78 | 87.7469 | 1.1250 |
| Pearson Chi-Square | 78 | 73.0603 | 0.9367 |
| Scaled Pearson X2 | 78 | 73.0603 | 0.9367 |
| Log Likelihood |  | 268.1419 |  |
| Full Log Likelihood | -160.0474 |  |  |
| AIC (smaller is better) | 332.0948 |  |  |
| AICC (smaller is better) | 333.2000 |  |  |
| BIC (smaller is better) |  | 346.6078 |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the $5 \%$ level of significance, $A C D$ and $D D$ are significant. The estimate $b_{1}$ and $b_{2}$ are positive, indicating that the predicted crashes increase by the driveway and access points. Also, and the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 87.74 , and 73,06 respectively, and the degrees of freedom is 78 indicating that the model is well fitted.

### 3.2 The Second Step

In this step, some other segments were added to the sample to improve models, and the total number of road segments increased to 105 segments. The previous SPFs were calibrated again on a new sample, and the results are summarized in the following.

### 3.2.1 Speed SPFs

### 3.2.1.1 SPF (1 ${ }^{\text {st }}$ trail $)$

In this SPF, length, AADT, and average V50 of lanes are considered as independent variables, and the results are as follow:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 50 \tag{3-15}
\end{equation*}
$$

Table 3-16 Summary of results of estimation for SPF (1st trail)

| Analysis Of Maximum Likelihood Parameter Estimates |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence <br> Limits | Wald Chi- <br> Square | Pr > ChiSq |
| Intercept | 1 | $a_{0}$ | -3.9299 | 3.3908 | -10.5758 | 2.7161 | 1.34 |
| $\ln (\mathrm{AADT})$ | 1 | $a_{1}$ | 0.7701 | 0.3413 | 0.1011 | 1.4391 | 5.09 |
| $\ln (\mathrm{~L})$ | 1 | $a_{2}$ | 1.8141 | 0.2264 | 1.3705 | 2.2578 | 64.22 |
| V50 | 1 | $b_{1}$ | -0.0019 | 0.0038 | -0.0093 | 0.0055 | 0.25 |
| Dispersion | 1 | $1 / \varphi$ | 0.5065 | 0.1261 | 0.3109 | 0.8252 |  |

| Criteria For Assessing Goodness of Fit |  |  | Value/DF |
| :---: | :---: | :---: | :---: |
| Criterion | DF | 101 | 112.8785 |
| Deviance | 101 | 112.8785 | 1.1176 |
| Scaled Deviance | 101 | 106.1085 | 1.1176 |
| Pearson Chi-Square | 101 | 106.1085 | 1.0506 |
| Scaled Pearson X2 |  | 281.0171 |  |
| Log Likelihood | -224.8484 |  |  |
| Full Log Likelihood |  | 459.6968 |  |
| AIC (smaller is better) |  | 460.3029 |  |
| AICC (smaller is better) |  | 472.9666 |  |
| BIC (smaller is better) |  |  |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the $5 \%$ level of significance, the intercept and $V 50$ are not significant. The estimate $b_{1}$ in Table 3-16 is negative, indicating that the predicted crash frequency decreases with speed, which is not reasonable because, by increasing speed, the probability of a crash occurring should increase, so the sign of $b_{1}$ should be positive. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 112.87, and 106.11 respectively, and the degrees of freedom is 101 indicating that the model is well fitted.

### 3.2.1.2 $\operatorname{SPF}\left(2^{\text {nd }}\right.$ trail $)$

In this SPF, length, AADT, and average V85 are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 85 \tag{3-16}
\end{equation*}
$$

Table 3-17 Summary of results of estimation for SPF (2nd trail)

| Analysis Of Maximum Likelihood Parameter Estimates |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence <br> Limits | Wald Chi- <br> Square | Pr > ChiSq |
| Intercept | 1 | $a_{0}$ | -3.9560 | 3.4034 | -10.6266 | 2.7145 | 1.35 |
| $\ln (\mathrm{AADT})$ | 1 | $a_{1}$ | 0.7729 | 0.3417 | 0.1033 | 1.4426 | 5.12 |
| $\ln (\mathrm{~L})$ | 1 | $a_{2}$ | 1.8139 | 0.2266 | 1.3697 | 2.2580 | 64.06 |
| V85 | 1 | $b_{1}$ | -0.0017 | 0.0038 | -0.0091 | 0.0057 | 0.21 |
| Dispersion | 1 | $1 / \varphi$ | 0.5077 | 0.1263 | 0.3118 | 0.8266 |  |

Criteria For Assessing Goodness of Fit

| Criterion | DF | Value | Value/DF |
| :---: | :---: | :---: | :---: |
| Deviance | 101 | 112.8052 | 1.1169 |
| Scaled Deviance | 101 | 112.8052 | 1.1169 |
| Pearson Chi-Square | 101 | 105.9862 | 1.0494 |
| Scaled Pearson X2 | 101 | 105.9862 | 1.0494 |
| Log Likelihood |  | 280.9929 |  |
| Full Log Likelihood |  | -224.8726 |  |
| AIC (smaller is better) |  | 459.7452 |  |
| AICC (smaller is better) |  | 460.3512 |  |
| BIC (smaller is better) |  | 473.0150 |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the 5\% level of significance, the intercept and $V 85$ are not significant. The estimate $b_{1}$ in Table 3-17 is negative, indicating that the predicted crash frequency decreases with speed, which is not reasonable because, by increasing speed, the probability of a crash occurring should increase, so the sign of $b_{1}$ should be positive. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 112.80, and 105.99 respectively, and the degrees of freedom is 101 indicating that the model is well fitted.

### 3.2.1.3 SPF (3 ${ }^{\text {rd }}$ trail)

In this SPF, length, AADT, V50, and V50SD are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 50+b_{2} \cdot V 50 S D \tag{3-17}
\end{equation*}
$$

Table 3-18 Summary of results of estimation for SPF (3rd trail)

| Analysis Of Maximum Likelihood Parameter Estimates |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence Limits | Wald Chi- <br> Square | Pr > ChiSq |
| Intercept | 1 | $a_{0}$ | -4.1384 | 3.3192 | -10.6438 | 2.3671 | 1.55 |
| $\ln ($ AADT $)$ | 1 | $a_{1}$ | 0.8198 | 0.3357 | 0.1618 | 1.4778 | 5.96 |
| $\ln (\mathrm{~L})$ | 1 | $a_{2}$ | 1.7477 | 0.2243 | 1.3081 | 2.1874 | 60.71 |
| V50 | 1 | $b_{1}$ | -0.0038 | 0.0039 | -0.0114 | 0.0038 | 0.96 |
| V50SD | 1 | $b_{2}$ | -0.0681 | 0.0447 | -0.1557 | 0.0194 | 2.33 |
| Dispersion | 1 | $1 / \varphi$ | 0.4761 | 0.1222 | 0.2879 | 0.7873 |  |

Criteria For Assessing Goodness of Fit

| Criterion | DF | Value | Value/DF |
| :---: | :---: | :---: | :---: |
| Deviance | 100 | 113.8664 | 1.1387 |
| Scaled Deviance | 100 | 113.8664 | 1.1387 |
| Pearson Chi-Square | 100 | 118.4218 | 1.1842 |
| Scaled Pearson X2 | 100 | 118.4218 | 1.1842 |
| Log Likelihood |  | 282.1574 |  |
| Full Log Likelihood |  | -223.7081 |  |
| AIC (smaller is better) |  | 459.4162 |  |
| AICC (smaller is better) |  | 460.2734 |  |
| BIC (smaller is better) |  | 475.3400 |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the $5 \%$ level of significance, intercept, $V 50$, and $V 50 S D$ are not significant. The estimate $b_{1}$ and $b_{2}$ in Table 3-18 are negative significant indicating that the predicted crash frequency decreases with speed, which is not reasonable because, by increasing speed, the probability of a crash occurring should increase, so the sign of $b_{1}$ should be positive. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 113,87 and 118.42 respectively, and the degrees of freedom is 100 indicating that the model is not well fitted compared to the previous models.

### 3.2.1.4 SPF (4 $4^{\text {th }}$ trail $)$

In this SPF, length, AADT, average V85 of lanes, and standard deviation of V85 are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 85+b_{2} \cdot V 85 S D \tag{3-18}
\end{equation*}
$$

Table 3-19 Summary of results of estimation for SPF (4 th trail)

| Analysis Of Maximum Likelihood Parameter Estimates |  |  |  |  |  |  |  |  |

| Full Log Likelihood |  |  |  |  |  | -223.5733 |  |  |
| AIC (smaller is better) |  |  |  |  |  | 459.1466 |  |  |
| AICC (smaller is better) |  |  |  |  |  | 460.0037 |  |  |
| BIC (smaller is better) |  |  |  |  |  | 475.0703 |  |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the 5\% level of significance, intercept, V85 and V85SD are not significant. The estimate $b_{1}$ and $b_{2}$ in Table 3-19 are negative significant indicating that the predicted crash frequency decreases with speed. Also, The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 113,87 and 117.75 respectively, and the degrees of freedom is 100 indicating that the model is not well fitted compared to the previous models.

### 3.2.1.5 SPF ( $5^{\text {th }}$ trail )

In this SPF, length, AADT, and V50Max are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 50 \max \tag{3-19}
\end{equation*}
$$

Table 3-20 Summary of results of estimation for SPF (5th trail)

| Analysis Of Maximum Likelihood Parameter Estimates |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Parameter | DF | Estimate | Standard <br> Error | Wald 95\% <br> Confidence <br> Limits | Wald Chi- <br> Square | Pr > ChiSq |  |
| Intercept | 1 | $a_{0}$ | -3.8373 | 3.3813 | -10.4646 | 2.7900 | 1.29 |
| $\ln$ (AADT) | 1 | $a_{1}$ | 0.7647 | 0.3402 | 0.0979 | 1.4316 | 5.05 |
| $\ln (\mathrm{~L})$ | 1 | $a_{2}$ | 1.8130 | 0.2256 | 1.3709 | 2.2552 | 64.59 |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the $5 \%$ level of significance, the intercept and $V 50 \mathrm{max}$ are not significant. The estimate $b_{1}$ in Table 3-20 is negative, indicating that the predicted crash frequency decreases with speed. Also, $\ln (\mathrm{AADT})$ and $\ln (\mathrm{L})$ are significant at the $5 \%$ level of significance. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 113.10, and 106.86 respectively, and the degrees of freedom is 101 indicating that the model is well fitted.

### 3.2.1.6 SPF (6 ${ }^{\text {th }}$ trail )

In this SPF, length, AADT, and V85Max are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 85 \max \tag{3-20}
\end{equation*}
$$

Table 3-21 Summary of results of estimation for SPF (6 th trail)

| Analysis Of Maximum Likelihood Parameter Estimates |  |  |  |  |  |  |  |  |

| AICC (smaller is better) |  |  |  |  |  | 460.2039 |  |  |
| BIC (smaller is better) |  |  |  |  |  | 472.8677 |  |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the $5 \%$ level of significance, the intercept and $V 85 \mathrm{max}$ are not significant. The estimate $b_{1}$ in Table 3-21 is negative, indicating that the predicted crash frequency decreases with speed. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 113.10, and 106.91 respectively, and the degrees of freedom is 101 indicating that the model is well fitted.

### 3.2.1.7 $\operatorname{SPF}\left(7^{\text {th }}\right.$ trail $)$

In this SPF, length, AADT, average V50, V50SD, V50max are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 50+b_{2} \cdot V 50 S D+b_{3} \cdot V 50 \max \tag{3-21}
\end{equation*}
$$

Table 3-22 Summary of results of estimation for SPF (7th trail)

| Dispersion | 1 | $1 / \varphi$ | 0.4711 | 0.1218 | 0.2838 | 0.7821 |  |

Criteria For Assessing Goodness of Fit

| Criterion | DF | Value | Value/DF |
| :---: | :---: | :---: | :---: |
| Deviance | 99 | 114.0496 | 1.1520 |
| Scaled Deviance | 99 | 114.0496 | 1.1520 |
| Pearson Chi-Square | 99 | 116.3583 | 1.1753 |
| Scaled Pearson X2 | 99 | 116.3583 | 1.1753 |
| Log Likelihood |  | 282.3399 |  |
| Full Log Likelihood | -223.5256 |  |  |
| AIC (smaller is better) | 461.0512 |  |  |
| AICC (smaller is better) |  | 462.2058 |  |
| BIC (smaller is better) |  | 479.6289 |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the above table, at the $5 \%$ level of significance, the intercept, $V 50, V 50 S D$, and $V 50 \max$ are not significant. The estimate $b_{1}$ and $b_{2}$ in Table 3-22 are positive, indicating that the predicted crash frequency increases with increasing speed. While the estimate $b_{3}$ in Table 3-22 is negative. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-Statistics models are 114.05, and 116.36 respectively, and the degree of freedom is 99 , indicating that the model compared to previous models is not well fitted.

### 3.2.1.8 SPF ( $8^{\text {th }}$ trail )

In this SPF, length, AADT, average V85 of lanes, the standard deviation of V85, and maximum V85 of lanes are considered as independent variables, and the results are the following:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot V 85+b_{2} \cdot V 85 S D+b_{3} \cdot V 85 \max \tag{3-22}
\end{equation*}
$$

Table 3-23 Summary of results of estimation for SPF (8 th trail)

Criteria For Assessing Goodness of Fit

| Criterion | DF | Value | Value/DF |
| :---: | :---: | :---: | :---: |
| Deviance | 99 | 113.9255 | 1.1508 |
| Scaled Deviance | 99 | 113.9255 | 1.1508 |
| Pearson Chi-Square | 99 | 116.3494 | 1.1752 |
| Scaled Pearson X2 | 99 | 116.3494 | 1.1752 |
| Log Likelihood |  | 282.4541 |  |
| Full Log Likelihood | -223.4114 |  |  |
| AIC (smaller is better) |  | 460.8227 |  |
| AICC (smaller is better) |  | 461.9773 |  |
| BIC (smaller is better) |  | 479.4004 |  |

* The significant variables are highlighted with green, and the other is highlighted with red.

According to the table, at the $5 \%$ level of significance, the intercept, $V 85, V 85 S D$, and $V 85 \max$ are not significant. The estimate $b_{1}$ and $b_{2}$ in Table 3-23 are positive and not significant at the $5 \%$ level of significance, indicating that the predicted crash frequency increases with increasing speed, while the estimate $b_{3}$ is negative. The estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-Statistic models are 113.92, and 116.35 respectively, and the degree of freedom is 99 , indicating that is not well fitted.

### 3.2.2 Geometric features SPFs

The SPFs calibrated in the first step were calibrated again on the new sample, and the results will be summarized in the following section.

### 3.2.2.1 $\operatorname{SPF}\left(9^{\text {th }}\right.$ trail $)$

For calibration of this SPF, AADT, length, M, PL, ACD, PCD, and DD were used, and the result is as follow:

$$
\begin{array}{r}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot M+b_{2} \cdot P L+b_{3} \cdot A C D+b_{4} \cdot P C D+b_{5} \cdot \\
D D \tag{3-23}
\end{array}
$$

Table 3-24 Summary of results of estimation for SPF (9 th trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence Limits | Wald Chi- <br> Square | Pr > ChiSq |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Intercept | 1 | $a_{0}$ | -6.5682 | 2.7390 | -11.9365 | -1.1999 | 5.75 |
| $\ln$ (AADT) | 1 | $a_{1}$ | 0.8981 | 0.2784 | 0.3525 | 1.4437 | 10.41 |

[^3]According to the table, at the $5 \%$ level of significance, significance $M, P L, D D$, and $P C D$ are not significant. The estimate $b_{1}$ is negative, indicating that the predicted crashes decrease
with the median presence. While the estimate $b_{2}$ is positive, which shows that the parking line is increasing the probability of crash occurrence. Nevertheless, the estimate $b_{3}, b_{4}$ and $b_{5}$ are positive, indicating that the predicted crashes increase by increasing pedestrian crossing, driveway, and access points. Also, the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 116.79, and 106.44 respectively, and the degrees of freedom is 97 indicating that the model is somehow well fitted.

### 3.2.2.2 $\operatorname{SPF}\left(10^{\text {th }}\right.$ trail $)$

For calibration of this SPF, AADT, length, PL, ACD, PCD, and DD were used, and the result follows:
$\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot A C D+b_{2} \cdot P C D+b_{3} \cdot P L+b_{4} \cdot D D$
Table 3-25 Summary of results of estimation for SPF (10 th trail)

| Analysis Of Maximum Likelihood Parameter Estimates |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence Limits | Wald Chi- <br> Square | Pr > ChiSq |
| Intercept | 1 | $a_{0}$ | -6.6935 | 2.7411 | -12.0659 | -1.3211 | 5.96 |
| $\ln$ (AADT) | 1 | $a_{1}$ | 0.9024 | 0.2787 | 0.3561 | 1.4487 | 10.48 |
| $\ln (\mathrm{~L})$ | 1 | $a_{2}$ | 1.4981 | 0.1778 | 1.1496 | 1.8466 | 70.99 |

[^4]According to Table 3-25, at the $5 \%$ level of significance, $P C D, P L, D D$ are not significant. The estimate $b_{2}$ and $b_{3}$ are positive, showing that parking lines and pedestrian crossing density increase the probability of crash occurrence. Nevertheless, the estimate $b_{1}$ and $b_{4}$ are positive, indicating that the predicted crashes increase by the increasing driveway and access points of the road segments. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance, and the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 117.56, and 109.14 respectively, and the degrees of freedom is 98 indicating that the model is not well fitted.

### 3.2.2.3 $\operatorname{SPF}\left(11^{\text {th }}\right.$ trail $)$

For calibration of this SPF, AADT, length, ACD, PCD, and DD were used, and the result is as follow:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot A C D+b_{2} \cdot P C D+b_{3} \cdot D D \tag{3-25}
\end{equation*}
$$

Table 3-26 Summary of results of estimation for SPF (11 th trail)
Analysis Of Maximum Likelihood Parameter Estimates

| Parameter | DF | Estimate |  | Standard <br> Error | Wald 95\% <br> Confidence Limits |  | Wald Chi- <br> Square | Pr > ChiSq |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Dispersion | 1 | $1 / \varphi$ | 0.2097 | 0.0796 | 0.0996 | 0.4411 |  |  |

Criteria For Assessing Goodness of Fit

| Criterion | DF | Value | Value/DF |
| :---: | :---: | :---: | :---: |
| Deviance | 99 | 117.3230 | 1.1851 |
| Scaled Deviance | 99 | 117.3230 | 1.1851 |
| Pearson Chi-Square | 99 | 110.2829 | 1.1140 |
| Scaled Pearson X2 | 99 | 110.2829 | 1.1140 |
| Log Likelihood |  | 298.3033 |  |
| Full Log Likelihood | -207.5621 |  |  |
| AIC (smaller is better) | 429.1243 |  |  |
| AICC (smaller is better) |  | 430.2789 |  |
| BIC (smaller is better) |  | 447.7020 |  |

[^5]According to Table 3-26, at the $5 \%$ level of significance, $D D$ and $P C D$ are not significant. The estimate $b_{1}, b_{2}$ and $b_{3}$ are positive, indicating that the predicted crashes increase by increasing pedestrian crossing, driveway, and access points of the road segments. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance, and the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 117.32, and 110.28 respectively, and the degrees of freedom is 99 indicating that the model is somehow well fitted.

### 3.2.2.4 SPF (12 ${ }^{\text {th }}$ trail)

For calibration of this SPF, AADT, length, ACD and DD were used, and the result is as follow:

$$
\begin{equation*}
\operatorname{Ln}(E(m))=a_{0}+a_{1} \cdot \ln (A A D T)+a_{2} \cdot \ln (L)+b_{1} \cdot A C D+b_{2} \cdot D D \tag{3-26}
\end{equation*}
$$

Table 3-27 Summary of results of estimation for SPF (12th trail)

| Parameter | DF | Estimate |  | Standard Error | Wald 95\% <br> Confidence Limits |  | Wald ChiSquare | Pr > ChiSq |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| BIC (smaller is better) |  |  |  |  |  | 443.1118 |  |  |

[^6]According to Table 3-27, at the 5\% level of significance, $A C D$ and $D D$ are significant. The estimate $b_{1}$ and $b_{2}$ are positive, indicating that the predicted crashes increase by the
increasing driveway and access points of the road segments. Also, $\ln (A A D T)$ and $\ln (L)$ are significant at the $5 \%$ level of significance, and the estimate of $a_{1}$ and $a_{2}$ are positive and significant, indicating that the predicted crashes increase with the traffic volume and segment length. The SD and Pearson $X^{2}$-statistic model are 116.91 , and 110.18 respectively, and the degrees of freedom is 100 indicating that the model is well fitted compared to previous models.

### 3.3 Summary of Results and Discussion

In the previous step, each model was analysed separately without considering the result of the earlier models. In this section, models will be compared with each other in two stages; At first, the results of SPFs of speed variables will be discussed. Then, the development of SPFs that were calibrated based on geometric variables will be presented. The results of the first group of SPFs are summarized in Table 3-28.

Table 3-28 The summary of the first group of SPFs

| SPF | Pr > ChiSq |  |  |  |  |  | Scaled <br> Deviance | Pearson <br> Chi- <br> Square | AIC | AICC | BIC | $1 / \varphi$ |

* The scaled deviance and Pearson Chi-square, in the table, represent the ratio between values of these tests and degree of freedom. The closer to one, the more well-fitted a model.
** The significant variables are highlighted with green.
According to Table 3-28, in the first phase of the study, speed covariates are significant at the $5 \%$ level of significance, and there are some well-fitted models such as SPF ( $3^{\text {rd }}$ trail) and SPF (4 $4^{\text {th }}$ trail); In these models the variance and average speed of lanes considered as the covariates. Also, the Criteria for Assessing Goodness of Fit show that the models are pretty well fitted. However, by adding other road segments to the sample in the second phase, the speed covariates are not significant anymore. Therefore, there is not any correlation between
speed variables and crash frequency. As a result, for the urban roads of Turin, speed variables are not suitable variables to describe crash frequency.

Some controversial studies in which speed contributes to crash occurrence: First, Garber et al. (2000) concluded a relationship between crash rates and the independent variables of the standard deviation of speed mean speed and flow per lane. Second, Quddus (2013) studied a series of relationships between segment-level average speeds, speed variation, and accident rates based on nonspatial and spatial statistical models using a panel data set obtained from a significant road network around London. Third, Xu et al. (2019) found that a more significant spatial and temporal speed variance increases the probability of crashes on an urban expressway. These case studies were done on highways and freeways around or outside of cities. In contrast, Turin is a small city, and its road network consists of narrow lanes and short road segments. According to the HSM (2010), SPFs predict the average crash frequency for a specific site type, so the results of the studies mentioned above cannot be compared with this case study. Because Turin's urban road segments are entirely different from those road segments, functionally and geometrically.

The results of the second group of SPFs are summarized in Table 3-29.
Table 3-29 The summary of the second group of SPFs

| SPF | Pr $>$ ChiSq |  |  |  |  | Scaled <br> Deviance | Pearson ChiSquare | AIC | AICC | BIC | $1 / \varphi$ |

* The scaled deviance and Pearson Chi-square, in the table, represent the ratio between values of these tests and degree of freedom. The closer to one, the more well-fitted a model.
** The significant variables are highlighted with green.
According to the above table, M, PL, and PCD are not significant at the $5 \%$ significance level in all models. Comparing models clarifies that the best model is related to SPF (12th trail); its variables are significant. Its goodness of fitting values represents that it is well fitted compared to the other models. Between geometric variables, access point density and driveway density were significant, and they have a high correlation with crash frequency. Considering, Sacchi et al. (2015) estimated that when the predicted traffic conflicts increase $1 \%$, predicted collisions increase $0.8 \%$, the result is rational because by increasing the number of access points and driveways, the number of conflict points increases.

Some studies on highways and rural roads predicted access point density as an influencing factor on the crash frequency which will be discussed. Mayora et al. (2003) claimed that the highway variables with the highest correlation with crash rates in Spain's two-lane rural roads are: access density, average sight distance, average speed limit, and the proportion of no-passing zones. Furthermore, Mayora et al. (2003) claimed that the highway variables with the highest correlation with crash rates in Spain's two-lane rural roads are: access density, average sight distance, average speed limit, and the proportion of no-passing zones. Then, Marizwan Abdul Manan et al. (2013) concluded that increased access points per kilometre and the average traffic volume are highly associated with increased motorcycle fatalities per kilometre. Although these results are related to rural roads, which are entirely different from this case study, it is a confirmation that the location of access points can be Hazardous.

In addition, Greibe (2003) concluded that explanatory variables describing the road environment, number of minor side roads (access point), parking facilities, and speed limit proved to be significant variables for predicting the crash frequency of road segments. Also, Sawalha et al. (2001) concluded that section length, traffic volume, unsignalized intersection density (access point density), driveway density, pedestrian crosswalk density, number of traffic lanes, type of median, and land use type significantly affected accident occurrence. These studies were done on urban roads, and they confirm that the access points and driveway density are influential factors on the higher the accident risk.

## Chapter 4

## 4 Conclusions

According to the World Health Organization, more than 1.35 million individuals are killed on roads worldwide every year. Between 20 and 50 million more people suffer non-fatal injuries, with many incurring a disability because of their injury. Both fatal and non-fatal crashes will cost more than 1.8 trillion dollars from 2015-2030. Due to the harmful effects of crashes, transportation safety has become an essential topic among transportation engineers. Describing crash phenomena can help to identify sites that have the highest potential for improvement.

Safety Performance function results from observational studies that provide a statistical relationship between the predicted number of crashes per specific period and roadway characteristics. An SPF is a regression model used in road safety to estimate the number of collisions per unit of time for different facility types such as intersections and road segments. The independent variables of the regression model are usually roadway and traffic features.

In Italy, approximately two-thirds of all crashes occur in urban areas, so identifying roadway and traffic factors that influence crashes occurring in such a context is an important area of research. According to the literature, there were no previous studies about parameters influencing crashes occurring in Italian urban areas, and in particular in Turin. Most earlier studies on North American roads were entirely different from Italian roads functionality and geometrically. As a result, the goal of this study is the calibration of SPFs by considering geometric and speed features of Turin's urban roads as influential factors and developing models such a way to be useful for Italian urban roads.

Before developing models, some steps were followed to gather and manage datasets, and different software was used to collect data sets, such as QGIS and Excel. There was some uncertainty on AADT because of strange fluctuation of traffic data along roads. To overcome this problem, the Modified Z-score method was used to detect and delete outliers of the AADT data set, leading to more reliable data. There were no reported data for geometric features of the road, so Google map satellite was used for extracting geometric features. About speed data, a model from Bassani et al. (2014) was used to estimate average and operating speed.

In this study, negative binomial distribution was considered probability (statistical) distributions of the number of collisions and the degree of overdispersion in a negative binomial model represented by a statistical parameter known as the overdispersion parameter. To calibrate SPFs, Generalized Linear Modelling (GLM) was used because of the discrete nature of crash frequency. The calibration of SPFs was performed in two steps; First, the SPFs were calibrated on 83 road segments of Turin, and then road segments were increased to 105 , and the calibration of SPFs was again on the new sample. Nevertheless, except segment length and AADT, speed and the geometrical characteristics of the road.

From the results of the research reported in this paper, the following conclusions were obtained:

1. based on statistical significance and goodness of fit of SPFs calibrated on speed data, there is a low correlation between speed and crash frequency. In addition, based on previous expectations, by increasing speed, the probability of a crash occurring will increase. In contrast, an opposite behaviour was found in this specific case study with a negative sign of regression parameters for speed covariates;
2. among geometry features, access density and driveway density have the highest correlation with crash frequency because they were significant in models related to geometric variables;
3. the best SPF was found at the 12th trail, in which AADT, Segment length, Access density, and driveway density were found statistically significant.

Despite the limitations of this study, such as the absence of data related to Property Damage Only (PDO) crashes, the results mentioned above can be a step forward to estimate crash frequencies of Italian urban roads. Furthermore, indicating the most contributing factors in crashes occurring can be a guideline to distinguish the most hazardous road segments and choose the best countermeasures to improve road safety of urban roads. Considering the high correlation between access point density and crash frequency, enhancing visibility and using traffic lights at access points can improve the safety level of the road segment in Turin. In addition, constructing service loads along main roads to minimize the conflict points between driveways and road segments can be practical.

Nevertheless, this study is just an onset to describe crash phenomena in Italian urban roads, and there is a long journey toward understanding and improving road safety. Future studies can collect detailed information about crashes such as driver gender, weather condition, vehicle speed, road condition, etc. The next step is calibrating the safety performance function to clarify influential factors describing crash phenomena.

## Acknowledgment.

The author would like to thank the Polytechnic of Turin for providing this opportunity. The author would also like to express his gratitude to Dr. Marco Bassani and Dr. Emanuele Sacchi for their assistance in this study.

Appendix 4：
In this part，the V85 and V50 estimation of the road segments results will be presented．

Table 0－4 V85 and V50 of segments
