#### Abstract

Order picking (OP) is the most costly and labour-intensive action in warehouses. Some scholars argue that OP could employ up to fifty five percent of overheads in a warehouse for firms handling large volumes of items that are shipped frequently.

It is becoming increasingly challenging for order picking systems designers because of increases in labour costs, limited space, and increasingly frequent small orders with short delivery times. Consequently, considerable effort is devoted to developing new, innovative picking solutions that reduce operation costs, increase productivity, optimize space utilization, and improve customer service levels.

This project aims to provide a new solution for order picking and innovative ideas about evaluating and comparing different autonomous vehicle storage and retrieval systems (AVS/RS) through a simulation study of the systems operation in an automated warehouse. Eurofork, an Italian company that makes handling equipment, proposed the project. After several years of hard work, Eurofork has become a reference in the logistic automation field because of its ability to make high-quality machinery.

The first step in developing this study was to carry out an analysis of theoretical background regarding the warehouse process, focusing on the order picking process, classification of the order picking systems and automated systems. Further referenced in the literature were studies concerning automated storage and retrieval systems (ASRS) modelling and simulation, also the topics on research done on Robotic picking performance in comparison to different sorts in development, and the demand for mixed pallets and problems building them. There are three chapters culminating with the new order picking system and simulation models followed by experiment results, conclusions, and references.

Keywords: Order Picking Process, Autonomous Vehicle storage and Retrieval system, , Robotic Arm, , ASRS vehicle, Mixed pallet, Flexsim Simulation, Robot picking, Order picking inside the warehouse, Order picking outside the warehouse.

## Acknowledgements

I would like to extend my gratitude to Professor Guilia Bruno and my co-advisor, Professor Franco Lombardi, for providing this opportunity for me to conduct this master thesis and for providing me with valuable feedback and constructive suggestions.

I would like to extend my heartiest thanks to Dr. Alberto Faveto for guiding me to develop the model in FlexSim software, patiently answering the questions I had, and setting a pathway for me to learn quickly and efficiently the principles necessitated by this study.

Last, but certainly not least, I would like to express my deep gratitude to my family and friends who have supported me unfailingly and relentlessly throughout my years of study.

## INTRODUCTION

## Chapter 1

The following chapters explain warehouse automation, order picking processes, classification of order picking systems, and how to improve order picking efficiency.

### 1.1 Background

Optimizing the performance of a supply chain can occur when all milestones of that chain are executing as efficiently as possible. 'Logistics,' thus, is the management of products and services, including all aspects of the flow between vendors and consumers. Storage points or warehouses are used in supply chains for fluctuating lengths of time. For this reason, warehouses are incredibly important (1).

Warehouses no longer have limited roles in storing or buffering items such as raw materials, in-process items and finished goods. Currently, warehouses offer such features as product consolidation, quality-checking, packaging, and information services in addition to handling merchandise and storing it.

Taking a look at (2), these storage areas can be described as places where products are paused to better match supply and demand or to consolidate them to reduce transportation costs and to provide customer service.

## Types of Warehouses

The three main types of warehouses are (3)

1. Distribution warehouses (products from one or many suppliers to many customers).
2. Production warehouses (for raw materials, semi-finished products and finished products in production plant).
3. Contract warehouses (servicing one or more customers).

According to review (4) the main warehouse activities can be classified in four stages.

1. Receiving
2. Storage
3. Order picking
4. Shipping.

### 1.2 Warehouse Automation

Automation of warehouses started around 1960 through automated storage and retrieval systems (AS/RS) which executed the storage processes in German warehouses. Although the picking process was still manual, it can now be fully automated by some systems. (5) The compound annual growth rate (CAGR) of the automated storage and retrieval system market between 2019 and 2024 is estimated to be $7.7 \%$, growing from USD 7.6 billion to USD 11.0 billion (6).

In the ensuing years multiple automated picking systems have been developed, and they have been categorised as shown in Figure 1. Nevertheless, as pointed out by the author (5), most of them have not been studied in academic literature, even though their use in warehouses increases.

Fig 1. Classification of Automated picking systems
Credit: Azadeh, Koster e Roy (2019)

### 1.3 Order Picking Process

Order picking, also known as Order Picking (OP), is one of our most common warehouse activities. The purpose of Order Picking is to retrieve the requested items from storage location so that the customer's wish can be fulfilled. The order picking process (OPP) is a very labour-intensive process in manual systems and a very expensive one in automated systems (7). It may take up to sixty percent of all work tasks in the warehouse (8). In a typical warehouse, the price of the OPP may be as much as fifty five percent of the total operating cost of the warehouse.

Fig 2. Design and control of warehouse order picking
Credit: De Koster, R., Le-Duc, T., and Roodbergen, K. (2007).

Following the review cited in "Design and Control of Warehouse Order Picking" (9). Fig 2 stated that order picking costs are projected to be as much as fifty five percent of the overall warehouse operating expenses. Therefore, underperformance in order picking will lead to unsatisfactory customer service and high operating costs. In this paper, we provide an overview of the literature on typical design and control problems faced in manual order-picking processes, particularly in regard to optimal layout design, storage allocation methods, routing methods, order batching and zone allocation.

Picking operators execute physical operations manually, semi-automated or fully automated. In manual picking operations, the picker moves to product storage locations and gathers the items desired by the customer. When using mechanical pick and place systems, the products are transported mechanically to the picker's position, and the picker gets the items he wants, products-to-picker. In an automatic pick and place system, the products are mechanically transported and picked up without any manual involvement.

In recent reviews (10) high expenses, constraints of the application domain, and the limited availability of OPSs have led to an absence of research on automated OPS. (3) the author argue that automation and robotic picking systems can only be used in unique situations, for example, when handling valuable, small, or delicate items.

This article (11) includes detailed information concerning the reasons for investing in picking process automation and offers a complete view of a variety of automated systems. There are a wide variety of automated equipment for case picking (ACP) such as traditional automated case picking, robot-based automated guided vehicle (AGV)/mobile robot case picking (CPS), conveyor-based solutions, automated storage and retrieval system (ASRS), gantry robot-based solutions and vertical cascading order release system, The warehouse management systems (WMS) and warehouse control systems (WCS) check on stock location and move inventory, overseeing materials flow, and controlling everything from order placement to delivery.

Based on review (9) they define order picking as a process in which goods must be assembled, and then ordered by customers, placing the stock directly in order lines, releasing the order downstream, and picking at the right time and place. So, OP is order fulfilment, which ranges from withdrawing items from storage to fulfilling a number of customer orders.

They describe (3) that the OPS within warehouses can be classified into three mains types with respect to level of automation.

1. Manual warehousing systems-picker-to-parts
2. Automated warehousing systems-parts-to-picker
3. Automatic warehousing systems-picker-less systems

In the review (Designing a Cellular based Fully Automated Case Picking System) (12) discussed in detail about Automatic cellular case picking system (ACCPS). ACCPS is a
new ACPS where all OP activities are wholly automated. It is designed for labouring with products in plastic crates, bins, boxes, or bins on a daily basis, and must meet exceptionally high-speed requirements. The methodology to solve OPS design problem by the author (13) and (11) which is used as the basis to solve the proposed ACCPS design problem.

The ACCPS design is based on the cases of incoming pallets with only one SKU per pallet. However, each pallet contains many stacks, and each stack contains many crates. Every four full stacks are gathered on one pallet by an automated palletizer.

When a customer order is positioned on the main conveyor, the stacks emerge from it in batches, and the structure and time of each batch depends on the product availability in the cells and the customer order. The assumption is that only one type of product is stored in the storage cell, and a replenishment is performed if the cell is empty, with the number of crates in the replenished pallet depending on the cell's capacity. The anticipated required pallets are prepared near the input point of the ACCPS. A new full pallet is fed to the entrance of the ACCPS. see fig. 3 .

Fig 3. Stages of ACCPS operating principle
Credit: Mohammed Ruzayqat (2016)

### 1.4 Classification of order picking systems.

Without a uniform classification of order picking systems, there are different classification grounds based on which order picking systems can be categorized. (9) reviewed a system that has a taxonomy based on the dynamic elements in the system, with a basic employing structure that employs both humans and machines. See Fig. 4.

Fig 4. Classification of the Order picking Systems
Credit: De Koster et al., (2007)

In Figure 4, a new classification using the four major decisions was proposed. who picks the goods-humans/machines, who is in the picking area-pickers/goods, whether conveyors link each picking zone and what picking policy is with (picking by order or by item) see Figure 5 .

Fig. 5 Classification of the Order Picking System
Credit: Dallari et al., (2009)

A number of order picking technologies and concepts are available today, and many solutions are available for improving accuracy, improving productivity, and boosting throughput. Nevertheless, there is still a great need for more improvements, more automation, and more strategies. Securing the best systems, the best technologies and the best processes remains the biggest challenge for OPS users.

## Chapter 2

The chapter describes the literature review of ASRS in detail regarding its picking process and mixed palletizing. An explanation of research results and papers has also been included in this chapter.

## 2.Literature review

### 2.1 Automated storage and retrieval systems

The author (14) summarizes an automatic storage and retrieval system (AS/RS) as a type of storage system that is exploited for laying products in storage and retrieving those products from storage in distribution and distribution environments. ASRS systems utilize a variety of computer-controlled technologies to handle pallets and store them in the warehouses. The fully automated, fully customizable system can handle pallets without human assistance.

In their explication, the authors also highlight some of the shortcomings of the new design, including the requirement of higher investments, and the inflexibility to change the physical layout (14).

ASRS comprises mainly of racks, which store goods; cranes, which transport, pick up, and return items; aisles, connecting spaces where cranes can cross over; input/output points, locations where retrieved goods are left and those to be stored are picked, pick positions, where the ordered goods can be picked from retrieved packages. There are many possible configurations for these components of the system, resulting in several types of AS/RS, as discussed in (14).

Fig 6. Overview of Automated Storage and Retreival System
Credit: Roodbergen and Vis (2009)
FIGURE 6 shows two alternatives in regard to the crane's movement and structure for loading and unloading. With respect to the equipment, it can be capable of handling only one load, termed a single shuttle, or deal with two loads at once, dual shuttle. They move the equipment between aisles, and the equipment in aisle-captive cranes travels between aisles, so each aisle requires one crane as well. Alternatively, aisle changers can transit goods across aisles. AVS/RS (14) is a special case of this in which autonomous vehicles may be retrieved in the case of a failure.

When it comes to AVS/RS, there are two options as to the shuttle movement. Tier-totier or Tier-captive. In the tier-to-tier system, vehicles can travel from one tier to another using the lift. However, in tier-captive systems vehicles are only allowed to travel from one tier to another and the lift only moves the loads, not the vehicles (15). One vehicle for each tier necessitates more vehicles, thereby making the tier-captive system more expensive, but it also has a higher performance compared to tier-to-tier system due to the independence of vehicles and lift. Allegedly, more efficient products are tier-captive single-aisle configurations according to the review (16).

In terms of the storage and retrieval components of the system, there are three options: two for the type of load stored and one for the way it is stored. It is possible to perform the picking activity by a person conveyed by the crane who will later pick the item up at the load's placement, sometimes called person-on-board. When the AS/RS is used, it can be at the picking location where the retrieved load is dropped off and the items of the customer's order gathered, this scenario is called an End-of-Aisle process, or AS/RS can deal with pallet or bin loads only, in which case the customer orders the whole load, thus there is no need to separate and separate items at the last moment. Also, depending on which type of load is being transported and handled, the AS/RS might be alluded to as a mini load AS/RS (14).

### 2.2 ASRS executing picking process.

In (17), the author recommended that one of the most useful ways to model ASRS is with simulation approaches.

On the one hand, warehouse systems can be best modelled using simulation techniques and on the other hand: using an analytical approach in order to simplify complex calculations and to achieve more accurate results, while modelling using simulation entails much more time to conceptualize and design. Significantly, performance is more reliably measured by the analytical models, even though they are not as precise as the simulation-based ones. Consequently, when numerous configurations need to be analysed, the analytical technique is preferred (5).

Regarding the review (18), they used simulation to help with the design, they emphasize that it is important to design the right autonomous vehicle storage and retrieval system from the start, since it is hard to modify it later due to its lack of elasticity. They achieved this by constructing a simulation model of the system on Arena 12.0 and reviewing the average cycle time for 21 simulated use cases.

To facilitate the design of the system, (19) author applied simulation to answer design questions. To design a rack, they built an optimal simulation model that can be reconfigured separately based on how many elevators and racks are needed. The authors used a virtual-reserve rack configuration to determine the throughput and cycle time of 81 various racks within 48 hours, for distinct retrieval rates.

By developing a research by the author (16), (20) not only the impact of diverse rack configurations was resolved, but also impacted by two other aspects: the velocity profiles of shuttle carriers and the table of gravity in elevators on the performance of a shuttle base storage system.

A Discrete event simulation was enacted to analyse the performance of the system by realizing the number of transactions happened in time on each scenario. The cases were created with 3 levels of aisles and 3 times the number of tiers and two distinct velocity profiles for the shuttle and the lift. According to the authors, the system's performance is substantially determined by two factors: the number of aisles and the throughput of the lift. Furthermore, the team noticed that although in general the bottlenecks are the lifts' lifting tables, when the number of columns is too high the shuttles could be the bottleneck depending on their pace.

Fig 7. Main components of AVS/RS
Credit: EKREN, Banu Y. et al (2010)

Another study examining optimal designs by simulation was implemented by the author (18), with the peculiarity being that they seek to obtain an optimal combination of lifts and autonomous vehicles (AVs), taking into account some pre-specified rack configurations. Arena 12.0 was used for the simulation analysis. Seven rack arrangements were considered, along with two arrival rates, and nine or ten possible arrival rates for each rate.

The authors computed the average cycles of storage and retrieval transactions and the average utilization for lifts and elevators by simulating these transactions. They came to a better understanding of the system's performance under several scenarios and found the best technique for attaining maximum efficiency without surpassing the limits set by the system.

In the literature, an additional approach to improving operations involves evaluating the system's performance under different conditions. In the review, (21) attempted to assess the performance of a mini-load multi-shuttle order picking system when the order structure varies. For evaluation purposes, they collected data about the system's throughput and average cycle time per order as well as other simulation results. After employing simulation and analytical tools (2), Giulia Bruno and D' Antonio assessed the warehouse's performance across several scenarios. The assessment in this case took into consideration the system's usage, the average time invested in queue by the unit loads, and the average number of queued units.

Based on the review, simulation was another tool used to compare different solutions in the literature. (22) devised an analytical model to maximize storage placement, taking into consideration the energy consumed for loading and unloading the units. After the evaluation was completed, the decision made by the analytical model and the original storage configuration were modelled and simulated on Flexsim software, which resulted in data about the stay time, congestion time, unloading quantity, and no-load period.

### 2.3 Mixed Palletizing

From the website (23) Palletizing mixed goods means placing products that are different sizes and types in a single container on a pallet. Because of the rising costs of transportation and logistics, it is becoming more common to use multiple pallets to accommodate as many items as possible.

Fig 8. Mixed Palletizing
Credit: Optimized logistic solutions.
Mixed Pallets made of multiple products, such as blends and bars, are produced in order to serve a single customer. The objective of giving these pallets is to cater to clientesses who need lesser volumes of products than a full pallet. The review concluded (24) at that time, there was already a tendency toward ordering uniform pallets to attend a certain period of time, to ordering mixed pallets for supplying the same interval at a greater frequency. Mixing pallets may be used by customers who want to order more often or because they are too low to order full pallets. On the other hand, vendors can use mixed pallets to infiltrate small markets more efficiently.
(24) author yaman helped a liquor producer to solve the issue of the need to produce mixed pallets. As the producer was selling numerous brands not all of which were well known, orders of certain brands did not reach full pallets of them. One of the primary barriers to offering customized pallets was the limited ability to offer mix pallets, so the customer chose either one of the few mix pallets, better accommodating their needs. This solution proved effective; it had lower inventory and backlog costs than was feasible with just full pallets.

According to review (24) there were some restrictions that hindered the option of creating customized pallets for each client; the authors write that there is no technology and the manual production would be too complex. In a previous article, it was emphasized that automation increases efficiency and that manual execution of the process might result in more damage and errors. Even though mixing pallets may be beneficial over time, warehouses and distribution centres may hesitate when they build it.

### 2.4 Research Results

In this section magazines, articles, research papers and related information are mostly focused on different kind of robots and their picking operations.

## Robotic Arm

In their publication 'Warehouse and Distribution Science' (25) explains that ASRS requires that human laborers be substituted by robotic vehicles that move in each aisle in the warehouse. These devices allow for movement in horizontal and vertical directions through a single command cycle or a dual command cycle, which enable the unit being stored or being recovered to be transferred.

Common robots used in manufacturing are the robotic arms. These metal arms have 4-6 joints, making them useful in many manufacturing processes, such as material handling and material removal.

Robots share many features with human arms - they have three joints - large wrist, petite wrist, elbow, and shoulder. The six-axis arm can move in six different ways, unlike an arm, which only has two joint places.

Fig 9. Robotic ARM

## Credit: VectorStock

Manufacturing with an industrial robot arm not only increases the speed of a process, but it also additionally enhances accuracy. These robotic arms reduce the employee error rate and labour expenses of manufacture. A robot arm is built by uniting two or more joints. It usually consists of steel and cast-iron material. Motors are affixed to each joint through a robotic controller. Some large arms applied to lift heavy payloads are mechanically manipulated.

With robotic arms, manufacturers manoeuvre the end effector from one position to another, easily taking down and putting up pieces or eliminating the entire equipment. These robotic arms can be designed to do a number of different tasks, or one specific task, based on the manufacturer regulations. They also use these robots to lift heavy objects.

## 1.Robots in warehousing

According to the document Robotics in Production presented by (26) Larry M. Sweet PhD , also an executive of Symbotic LLC in Orlando Marriot Centre, the robot's purpose is to assist manufacturing tasks.

Fig 10. High Sku count mixed case palletizing. Credit: Larry M. sweet (2013)

Fig 11. Traditional solutions for automated picking

Fig 12. Mobile robot explosion
Credit: Larry M. sweet (2013)

## Mobile robots' characteristics:

1. easy to re-configure.
2. 2 D vs. 3D layout topologies
3. Variable vs. fixed storage spacing.
4. Manual vs. automated product handling
5. Sequencing vs. non sequencing product flow

## 2. Robotics in the Warehouse: Changing the Fulfilment Paradigm from Logistics management magazine. (27)

Article by Locus Robotics August 27, 2019: Locus Robotics CEO Rick Faulk describes how robots can change the productivity and structure of any fulfilment centre and why thinking outside the box can engender better results.

This ground-breaking methodology is driving today's revolutionary change and illustrates the significant productivity gains and scalability advantages of multi-bot picking.

Locus Robotics offers autonomous mobile robots (AMR) for fulfilment warehouses which can be disassembled and moved very easily. Each robot carries out part of the picking and transporting as the humans carry out all of the carrying. Each employee fills an order on multiple robots as they proceed to line up to pick online orders.

Fig 13. LOCUS ROBOT
Credit: Logistics Management (2019)
An employee using conventional carts or a similar motorized follow bot-style cart is limited to the orders they can physically carry in a single robot. Furthermore, using a multi-bot model, everybody is free to work on their skill set. Because they can pick to any robot, pick volume is not hindered by the capacity of a single robot.

## 3. Warehouse robots for retail Automation

## Amazon Robots

According to (28), Amazon put retail automation technology in the spotlight with the 2012 acquisition of Kiva Systems. This company, based in Boston, developed warehouse robots, and related technologies, and it was acquired for $\$ 775$ million. Autonomous mobile robots that combine the effects of sophisticated control software, language perception, power control, computer vision, depth-sensing, machine learning, object identification, and semantic comprehension of user demands.

Fig 14. Amazon Robots in Warehouse
fig 15. Amazon Robots order picking Credit: Amazon Robots

Today's tech startups are attempting to fill the vacuum generated by Amazon's buyout of Kiva and some have been profiled in their feature on industrial warehouse robots. Companies like invia robotics, an emerging innovator against warehouse automation and the brains behind cobots (cooperative robots), are developing warehouse robots that can function right alongside humans.

## Invia Robotics

From the website (29) Since its foundation in 2015, InVia Robotics has rendered the next generation of warehouse automation solutions. They have taken in an undisclosed amount of financing to optimize a simple, intuitive, and inexpensive warehouse system while further enhancing your employees work environment.

Fig 16. inVia Runner and picker with a suction cup from article robotics and Automation

## Credit: Invia Robots

The inVia Picker and the inVia Runner are two distinct robots that manage logistics. The Runner is able to literally transport items from one place to another, which either an individual can do or a robot will do. The Picker gets stuff by draining it up using suction cups. Taking robots as an example, inVia Robotics Management Software was designed to automate the workplace procedures between people and robots with artificial intelligence by generating all the itineraries that increase efficiency in both parties.

## Skypod

Exoctec (30) based in Pittsburgh, was started in 2015 by former robotic and software engineers. Its robot armies can move like the Wonkavator, shifting up and down, sideways and slantways, in all directions, as well as frontways and squareways. It is also similar to the AVS/RS operation see fig 17. Technically, this can do this without having any intricate structures to support the robots.

Fig17. Skypod robot in Warehouse
Credit: Exoctec

Well, it is able to use a laser scanner to help it gather data across three-dimensional spaces, and that is how it can convert itself from horizontal to vertical. Skypod can ascend five times higher and move four times faster than traditional shelf-moving robots, it also can pick up twice as many items per hour and inhibit warehouse workers from walking at least 10 miles daily.

## Arming warehouse robots

A startup company (31) based in San Antonio, Texas, has developed a robot arm that can move dynamically, almost quite naturally, to pick up packages, unlike the average warehouse robot arm that normally does repeated actions from a static position.

Fig18. The Pick-One robotic arm from Plus-One Robotics is a view of what the robot sees. Credit: Plus One Robots

Digital cameras, developed into the Pick One's digital cameras, are capable of transmitting scans of made in China footwear in fractions of a second to select the right pick position for the arm, which can apply 25 picks per minute like a human.

## Swift Warehouse robots

In 2012, Pittsburgh-based IAM Robotics (32) was established. The company recently secured just under $\$ 1$ million for a warehouse robot based on the same platform and RobotiQ technology as Plus One Robotics. Swift is the firm's mobile control robot. It can travel through the warehouse autonomously and locate and locate products. It can then pick them up utilizing any of numerous grasping extensions that can lift up to 15 pounds.

Furthermore, their system encompasses SwiftLink software, which traces and supervises the robots, and Flash, a hightech inventory instrument that records a product's barcode, 3 D dimensions, weight and a high-resolution image of any item stored within it.

## Swisslog Carry star \& itempiQ

Swisslog (33) is a leading corporation amongst the Kuka group. They created a carrystage order fulfillment system. See figure 20, on how transporting orders works.

Fig 20. Carry star Process Description Credit: Swiss Log (2019)
Carry Star utilizes no conveyor technology or automatic equipment on-site, thus being a fully automated system. This design opportunity is optimal, as it allows for a large
number of alternatives for order fulfillment. The pallet builder robot will fabricate mixed pallets in roughly 200-300 layers an hour, and it can easily be configured on the basis of volume and product type.

Warehouse storage are able to receive pallets and retain carry star cells, although there is a lesser storage area near the building area then is utilized for pallet building. See Figure 21. Once the picking is done and the order is packed, locating the pallets for storage is not essential. They can be kept in the scheduled compartment until desired.

Fig 21. Carry star storage area

## Credit: Swiss Log (2019)

Additionally, the system integrates the Carry robots, guided vehicles for the aim of transporting pallets around the area, and the wrapping machine. The Carry robots follow the pathways in Figure 16. At the exit of the system is the wrapping machine. The robots advance the pallets they have prepared to the wrapping machine. The pallets are constructed and wrapped, then sent to the container.

Fig 22. Carry AGV and it taking the mixed pallet to the wrapping area Credit: Swiss Log (2019)

A Swisslog crew also supplied insights into how automation will generate increased productivity. During a recent automation project for AutoStore, the robots revolving up and down throughout the grid collaborate with each other to compensate for any downtime. In fact, ItemPiQ uses robotic automation technology used in challenging industrial environments. Blended with ItemPiQ, these systems offer the flexibility, availability and uninterrupted operation essential for 24/7 performance.

Fig 23. Autostore robot moving across the top of grid ItemPiQ Robot.
Credit: Swiss Log (2019)
ItemPiQ is intended for speed and reliability. Picking from an AutoStore bin and placing it in a target bin or carton, the robot runs at up to 1000 transactions per hour under ideal conditions. More conveyor systems will permit automatic relocation of the destination bin. Because ItemPiQ and AutoStore operate with the same platform, Swisslog's Sync, the system seamlessly interfaces. ItemPIQ has a standard interface that enables it to communicate with any WMS system accessible.

The grippers in SynQ are wise enough to understand through experience. When they encounter an item for the first time, they will automatically decide on the optimum way to grab it for them. In addition, the system would endeavor to recollect the last time the item was picked successfully and operate to develop upon the system in a way that results in a shorter cycle time and bigger pick success rates the longer the system has been running.

## Toru Robot

In the Interview (34) Toru Robots of Magazino authored last year, Moritz Tenorth was interviewed, a founder and CEO of MitiGi, an inventive startup for mobile pick-andplace robots that are then used to conduct specific item-level logistics operations. The Magazino team has constructed perception control-based mobile robots that could be exploited in warehouses or manufacturing plants. The TORU robot consists of a mobile base, a retractable shelf, and a retractable and rotatable column with a gripping mechanism. It can identify objects using 3D and 2D cameras. It can handle rectangular items for example shoe boxes and lexicons, store them on shelves, then deliver them to wherever the robot selects it is necessary.

Fig24. Toru robot is picking and storing items from rack Credit: Magazine by Toru Robots

Here's where TORU differs significantly from other systems: it does not demand custom warehouses or for manufacturers to retrofit existing warehouses to accommodate robots. Certainly, robots might indeed integrate into warehouses that already exist.

## 4.Warehousing and logistics Robot Shipments

A market intelligence business, Tractica (35) is part of Informa. It focuses on rapidly emerging technologies.

Fig 25 Warehousing and Logistics Robots
Credit: Article Tractica (2017)

The following figure 25 depicts Tractica Analysis survey of the warehouse and logistic robot's market. The report claims, (27) the warehouse and logistic robot's market is projected to expand by nearly $10 \%$ over the 2016-2021 period. In addition to valuing the most critical aspects that will influence the market, the report gives an analysis of the key market drivers and threats.

### 2.5 Research Papers

According to the paper "Performance evaluation of a new intralogistics systems" the author (36) had clearly discussed about the review of robot picking and building mixed pallets.

## Robotic automated storage and retrieval system mixed pallet build system.

Bastian Solutions is an independent material handling system integrator supplying automated solutions for distribution, manufacturing, and order fulfilment centres around the globe. Its current patent (37) describes a robot that can generate several types of pallets and integrates them into single pallets.

We use a mixed pallet-build system in fig 36 , that involves a series of pallet racks with multi segment dividers to store distinct assets and items. Most of the pallets will be the same items, but also the pallets can have varying stuff or be mixed. Further, different pallet build systems have robotic carts which can be moved vertically and horizontally among the racks in order to develop mixed pallets. Figure 27 shows a carriage that has an interior which can accommodate multiple pallets.

fig 26. Mixed pallet build system.
Credit: Patent by Bastian Solution LLC (2014)

Fig 27. The robotic Automated Storage and Retrieval System (AS/RS) Credit: Patent by Bastian Solution LLC (2014)

As each mixed pallet is assembled, the AS/RS carriage returns to the unloading area. Conveyors are activated to discharge the pallet onto the floor from the carriage AS/RS. With the assistance of pallet trucks and conveyors, pallets can be unloaded from the system discharge point or other mechanism. The turntables are installed on a threedimensional robotic AS/RS carriage with rollers, drag chains, locating grippers, or other conveying mechanisms. Pallets are stored on conveyor belts, which are loaded on by forklifts. The forklift unloads pallets, and then reverses the process to replenish other products. Several aisles of robotic AS/RS can be used concurrently for throughput.

Fig 28. Mixed pallet build system at loading/unloading area Credit: Patent by Bastian Solution LLC (2014)

Fig 29. mixed pallet build system contains multi-deep pallets of items in every rack Credit: Patent by Bastian Solution LLC (2014)

In this design, which is like the one demonstrated in figure 26, the rack can manage more than one pallet of identical, similar items. In other words, instead of a single pallet, there are several boxes at each level. Nevertheless, the function is the same as described above in figure 29.

This invention saves time since it does not demand to break down pallets, buffers or sequence each item. It furthermore assists save space in the warehouse, since complete pallets do not have to be crushed and mixed pallets are made of partial ones. It has also been demonstrated to be more cost-effective than other equivalent methods of the same type.

## Robot in a pallet support shuttle

Upon reading the review (38), from the patent by Axium Inc., which includes a shuttle to transport the pallets and possesses a robot that picks up items from full pallets kept in neighbouring stations. One of our primary concerns is that the system can only move horizontally along its path, needing the warehouse to harvest pallets from the shelves and place them along the feed conveyors that are situated near the shuttle's path. Although the robot can grab objects of varying sizes from pallets and use different implements, including vacuums, side grippers, forks, etc. this flexibility is beneficial to efficiency.

Fig 31. Robot picking in a shuttle system. Credit: Morency (2008)

## Automated Guided Vehicle (AGV) with Batch picking robotic arm

It was first patented by Bastian (39) in March 2017 using automated guided vehicles (AGV) which are deployed in warehouses and production environments to perform
various material handling functions without human interference. Commonly, these types of aids are exploited to improve safety and minimise overhead by reducing the number of employees needed to complete specific material handling duties.

Fig 32. Front elevation of an AGV system.

## Credit: Patent by Bastian Solution LLC (2017)

This figure 32 depicts the Drive Control System is equipped with a transport system for loading and discharging materials, such as totes, boxes, storage containers, SKUs, and other items, from and to the automated warehouse. The mechanism is constructed from a frame upon which a loader and an actuator can move in a vertical orientation, with the actuator containing (EoAT) engagement tools that grasp or otherwise engage the environment, Totes, for example, are put by the Robotic arm on the freight table. The robots have electro-mechanical grippers to load, unload, and reposition the totes on the loading table. The robots use detectors such as vision systems for smooth motion and exchanges with objects.

It mounts a loading table on the AGV. It is configured to accommodate several storage boxes. A frame stretches from the AGV, attaching the robot to that frame. The robotic
arm's frame is built from a gantry which allows it to revolve in relation to the rest of the AGV, and the arm can also move toward or away from the gantry. AGV's can hold multiple storage containers, making picking or placing easier. The gantry is handy for hands-on manipulation.

Fig 33. AGV planted to service a station performing batch picking. Credit: Patent by Bastian Solution LLC (2017)

In reality see fig 34 of an AGV, which are the examples produced by Bastian Solutions, the robotic batch picking, and the robot palletized.

Fig 34. batch picking by Robot and AGV picking with robotic arm.

## Chapter 3

In this chapter the statement of problem, objective of thesis and about methodology is discussed.

### 3.1 Statement of the problem

It has been previously studied by literature and research results relating to the storage and retrieval of products in warehouses. But the innovative project now emerges from Eurofork, which is innovating an intralogistics system that no one has seen before. ASRS delivered one new system which wholly utilized the shuttle and neither shuttle nor ASRS is needed anymore. A robot arm attached to shuttle will be deployed instead of shuttle up until transport as in current mobile devices.

Another company is wondering whether or not it would benefit from switching systems since multiple factors affect the economy of a system, such as the number of stock keeping units (SKUs), the number of orders and the length of time the ordering operation takes.

The purpose of this thesis is to compare the performance of automatic storage and retrieval systems in various scenarios. The aim of these comparisons is to assess if there is a better performance presented by the new system in multiple scenarios set in a synthetic atmosphere.

Given the early stages of the product development, the system has not been tested in a real-world environment. Accordingly, the problem addressed in this thesis is a comparison of two types of automated storage and retrieval systems under different scenarios. The thesis is formatted to make it simpler to read.

The proposed model is addressed as Eurofork's system, the other as new. For comparison, the models are described as OP for inside and outside the warehouse, respectively.

### 3.2 Objective of Thesis

The Italian company Eurofork offers an intriguing innovation, they propose a new way of making mixed pallets which is called a mixed pallet scheme. Because Eurofork is an Italian company that generates automated warehouses they are skilled in handling. The company's expertise in the area of manufacture of telescopic forks and its ability to produce a large quantity of telescopic forks sets it apart from the competition amongst its competitors. Further, it has developed its Esmart-shuttle division which practices the design and engineering of warehouse shuttle systems.

The ultimate objective of this thesis will be to model and develop a new innovative order picking system with an automated storage and retrieval system vehicle with a robotic arm that permits the construction of mixed pallets in the automated warehouse in order to fulfill orders.

There are two distinct objectives that will be elaborated in this study. One of the goals of this project is to evaluate new picking systems against Eurofork's one. The other aims to evaluate and compare the performance of two autonomous vehicle storage and retrieval system, which is building a mixed pallet inside the warehouse and outside of it.

As a means of achieving this objective, a warehouse storage and its operation will be simulated in a software program, Flexsim, providing performance measures as outputs. After obtaining all the required results, a comparison in between two ASRS simulation models will be then permitted to verify which one performs better.

## Chapter 4

In this chapter, Eurofork's system, new system, components and requirements are discussed.

### 4.1 Eurofork's System

Several warehouses have racks that contain shelving with similar pallets and boxes. When the customer requests an order, the picking process starts by picking multiple pallets. Once the multiple pallets are picked, they are clustered into a single pallet. Since the Eurofork (40) Company has AVS/RS with shuttle-based system for order picking can be seen the figure 36 .

Fig 36. Esmart Shuttle used in AVS/RS is loading/unloading a pallet.
Credit: Eurofork

## System description

Three main types of vehicles are used in the AVS/RS:

1. A vertical lift that moves vertically and allows access to different rack tiers.
2. A shuttle making its way through the aisle of the operating tier.
3. A satellite drives itself through the channels in the rack to store and retrieve pallets.

The satellite loads the pallet into the rack for storage, and the shuttle follows. Consequently, the two vehicles travel under the lift, which moves vertically in the direction of the final destination at which point the shuttle departs the lift. After traveling through the aisle, the shuttle gradually pulls the satellite along the channel towards the destination, then pulls out of the channel.

As the satellite starts moving forward along the channel towards the destination, chosen according to a LIFO protocol, the satellite drops the pallet as soon as it reaches the location. The automated shuttles transfer similar pallets from rack space to the picking station, where the robot collects the ordered items from similar pallets and assembles the pallet.

## New system

Esmart-shuttle is an intralogistics system that makes picking less complicated and makes the process simpler and faster. As more pallets are being constructed with mixed contents rather than full pallets, here we will discuss a method not based on shuttles.

The ASRS vehicle will find the pallets on its location with an attached robotic arm, assembling the products according to their positions rather than retrieving them to picking stations. See figure [37] \& [38]. Therefore, it intends to speed up the delivery process by eliminating the need for retrieving the entire pallet and then storing it again once the product is picked. Besides that, it aims to increase the system throughput and reduce transit charges.

## Order fulfilment process

1. The client requests an order.
2. The ASRS vehicle advances to the destination rack with empty pallets.
3. An ASRS vehicle with an attached robot arm begins to pick products from similar pallets on a rack and place them on the empty pallet.
4. After the robot picked the products, the empty pallet is loaded with various products, thus forming the mixed pallet.
5. The customer will receive a mixed pallet from the shipping department once it has been processed to fulfill your order.
6. A simulation tool, Flexsim, can be used for the development of a process in this type.

Fig37. An example of new technique with Robotic Arm attached to ASRS vehicle.
Credit: Flexsim

Fig38. mixed palletizing snapshot
Credit: Flexsim

### 4.2 Components and Requirements

As part of an automated warehouse considering our new ASRS system, there are a few components, which were used for the development of the simulation models in software flexsim. They are described below.

1. Rack
2. ASRS Vehicle
3. Robotic Arm
4. Pallet
5. SKU's

## Rack

Storage and racking is an integral component of warehouse infrastructure, as it can obstruct or accelerate warehouse operations. Warehouse layout influences racking greatly by defining aisle widths, shipping areas, and storage space. Warehouse racking system configurations include selective racks, drive-in and drive-through systems, pushback, and flow-rack systems.

A software flexsim rack is stationary and double deep. The main features of the rack are its dimensions, which describes the height and depth of the rack, number of arrays in X and Z directions, number of rows per bay, and the width of the slots and bays. Order picking takes place in the rack.

## ASRS vehicle

As the name suggests, the automated storage and retrieval system works with racks. ASRS vehicles are specific types of vehicles developed for operating with racks. They can glide back and forth between the racks picking items up or dropping them off. They implement offset travel by only traveling along their own x-axis. As the offset travels, it will reach perpendicular with the destination location, lifting its platform too. If the offset travel is for a load or unload task, then as soon as the offset travel is complete, the flow item will continue on its platform, or off of its platform to its destination spot, using the user-specified loading/unloading time.

The new system uses the task executor to retrieve loads from the destination rack using a robotic arm.

## Robotic Arm

The robot must lift flow items from their starting points and place them at their ending points. Commonly, the base of the robot cannot move. Instead, six joints revolve the flow items. In addition, it executes multiple tasks that require a rotation of its joints. In the Aspect system it is attached to the ASRS vehicle to attain the destination rack to carry out order picking and to place the items on the pallet in order to build mixed pallets.

## Pallet

Pallets are flat fragments of wood used to lay down foundations for the distribution of goods. The pallet stores protects and transports goods that are handled by the materials handling equipment such as forklifts and pallet jacks.

Pallets are bulky goods units that can be stacked on top of each other and stored in racks with the same piece of product, depending on the amount ordered. In the new system, the order picking process is done by ASRS vehicle with robotic arm to mix SKUs into pallets to meet client requirements.

## SKU

Inventory management relies on an SKU to keep track of inventory items, notably color, size, and variants. Inventory management in conjunction with an SKU helps to identify inventory items over lists, invoices, manufacturing orders, and purchase orders.

With the new system, we have 20 distinct types of SKUs, which symbolize 20 different types of boxes, and they are stacked in their assigned slots with their corresponding quantities.

The FlexSim software was used to develop a simulation model based on the five component requirements, their interactions, and the packaging and palletizing requirements. According to Euroforks Inc., palletizing is a crucial procedure for the manufacturing process. In the new system it does not require palletizing area to execute the process of shipping to another pallet since the trolley picks all the items ordered and assembles the pallets.

### 4.3 System Operating

As such, it is a task that is similar to ASRS vehicles and robotic systems in its design, but order picking system is a devilishly tricky undertaking due to the enormous amount of design limitations and variables. Solving these difficulties requires integrating information about the number of sku's, number of orders, order filling times, and internal constraints into each process step from the moment the product arrives at the warehouse to the moment the product departs for shipment.It focuses
on the pallets that are stored on the rack with the same sku per pallet and builds mixed pallets with different sku's for the individual orders.

The flowchart Fig 39 illustrates the way order picking occurs as shown in the receiving procedure in the flexsim software. The process starts at receiving and begins with laying homogeneous pallets with a given quantity and in a specific slot in a particular bay and area.Whenever the order picking operation takes off, the volume on the pallets will decrease. As a result, the rack filling process is implemented in the same periods of time as the FCFS method, ensuring that the rack never runs empty.

Fig 39. Flowchart of new order picking system.

This flow chart suggests that the customer order request starts the process and then all the steps need to be completed. In the process, we assumed a robotic arm is connected to the ASRS vehicle to pick the items from stored pallets, as it would not be so convenient to execute manually. During the journey, the robotic arm picks the empty pallet from the picking area and places it on its platform. Meanwhile, along with the vehicle asrs, a robotic arm can pick the ordered sku from stored pallets and place them on the pallet.

ASRS containerized vehicles travel horizontally throughout aisles, pulling their platforms to the target bay and level of the rack for order picking. Once all the items are picked, an empty pallet is put together from various kinds of items, then put into a mixed pallet that will be stored next to the packaging area for storage.

## Chapter 5

This chapter is all about Model conceptualization and explanation of 3D simulation models which implements new order picking.

### 4.3 Model Conceptualization

Conceptualizing the model is important to the development of a realistic model and the goal of the project. It involves many elements that are necessary to evaluate the performance of the new simulation model.

In this thesis, there are two simulation models developed using software flexsim to perform a pick-and-place operation in an automated warehouse. An excellent 3D simulation provided by flexsim, a powerful, versatile, and user-friendly tool, allows you to model and enhance existing and proposed systems. This software is employed in manufacturing industries in assorted production, assembly line, job shop and in material handling such as conveyor systems and material handling machinery, AGV, packaging, warehousing, mining, logistics etc.

It largely contributes to enhancing the effectiveness of products, staffing, resource allocation, floor design, and asset management in an enterprise, and many companies have been implementing the software to improve techniques for allocating resources efficiently and also to reduce expenditures. A final profit is that a stakeholder communication tool delivers an effective manifestation of new proposed changes to a business system.

Comparison implies both simulation models must perform experiments to get the results determining the performance through their output.

Process simulations can be constructed in Flexsim that work with process flows. Process flows include tools in flexsim that help us define logic in a project. This spares us hundreds of hours in project simulation and helps us model complex systems quickly.

If you are in the early stages of an improvement project, it is difficult to know what model you should chase. Michael Belote says, "You can get an idea at the high-level of which brainstormed idea will provide the best output, and then you can do detailed models in a much more focused way".

As you use Process Flow, the logic can be placed in one location, using its library attributes like Task sequences, Shared assets, Task Executors, etc. As you create logic with Process Flow, connectors may be created to carry it out correctly, allowing the 3D simulation model to function correctly.

### 5.2 Explanation of 3D simulation model

The main objective of the project is to perform "order picking to build mixed pallets" to accomplish this goal simulation models are used to run their experiments and compare results to choose which model had better performance. Two simulations have been developed but are not yet implemented.

1. Order picking inside the warehouse.
2. Order picking outside the warehouse.

### 5.3 Order picking Inside the warehouse.

This model performs order picking inside the warehouse to build the mixed pallet by using the logic created with process flow see figure 40.

Fig 40: 3D layout of order picking inside the warehouse.

## Credit: Flexsim

The layout of order picking inside the warehouse 3D simulation implemented with the process flow technique which has the following steps.

1. Arrival slot check
2. Random order creation
3. Order picking in the warehouse.

In the first stage, the rack storage can be the first step. See figure 41. In the flow chart of arrival slot check, the entire process of fulfilment is described in step by step. In our model, the rack has 20 bays with 10 levels and 2 slots per bay, each. We would be wondering how to store the sku's in the rack, right? Initially, the simulation starts with two arrivals defined in the source of quantity with the quantity of thousand items of twenty kinds of sku's per source.

There are thousand items which will be divided into ten bays and get placed in their designated slots approximately after 30 seconds of delay. Furthermore, they will remain at the same destination location in its own respective SKU over the whole duration of the delay.

## Arrivals Slot Check

Fig 41. Arrivals slot check

## Credit: Flexsim

The quantities of items are decreased when order requests are served, in consequence the sku's quantities are also reduced. In this system the quantity is updated as items are picked from the stored pallets in their place of delivery. When the quantity reaches zero, it is set back to the number of items available in a full pallet.

On the basis of this logic the arrival slot check process will again repeat the same logic to fill the rack by following all the steps starting from, locating a place to store the sku's with the same quantity, choosing the destination bay and slot and transferring the items into their storage slots.

Fig 42. Random order creation and OP in the warehouse

## Credit: Flexsim

In fig 42., you can see the synopsis of order creation and order picking is a snapshot of it as integrated in Flexsim (https://www.flexsim.com) to minimize the computational time, the process flow tool was applied. An interactive flowchart environment that can be used to develop model simulations in a short time with negligible computational effort. The top operation is ordering which handles order requests.

Every 70 seconds, orders are produced randomly using a random order seed used to create only one order at a time; once it has been created it is assigned with an order number and different type of sku along with quantity, and all the order data will be automatically presented and saved in an order history.

In order to execute order picking in the warehouse, there are three main resources: the pallet area, the picker, and the Arm. These three assets work together to complete the picking process. Picking area is where the pallet is picked, and picker is an ASRS vehicle and Arm is the robot. Once the order has been produced, the pallet is established at the picking area, and then picker (ASRS vehicle) will travel to the picking area and reach for the pallet.

We assumed that this arm was an ASRS component attached to the retrieval vehicle, thus starting the retrieval process along with the vehicle following the FIFO procedure. The vehicle enters the zone and then loads the item onto the pallet which is on the platform. It only displays one item at a time once picking all the ordered sku's from stored pallets. After picking all of them it then leaves the zone and makes the mixed pallet.

The sub flow will have order data such as order number, sku type, sku quantity, and order completion time. In this model, each order contains the maximum quantity of 1 unit to 4 units per sku. All these data are compiled in order history for every order and batch them to form a cycle. Cycle times are used to compute performance measures under different scenarios. Picking order inside the warehouse will be done when the mixed pallet is ready to be removed from the vehicle and later is placed into the pallet storage area to be shipped.

### 5.4 Order picking outside the warehouse

To build the mixed pallet, this model utilizes the logic set up in the process flow to pick orders outside the warehouse. This process has cache zones to organize order picking.

Fig 43: 3D layout of of order picking outside the warehouse (Cache Zone) Credit: Flexsim

Within the design of order picking inside the warehouse, the 3D simulation was implemented with the process flow technique with additional steps.

1. Cache initialization
2. Arrival slot check
3. Cache Refill
4. Random order creation

## 5. Order picking in the cache zone

Figure 44 illustrates the system's initialization with cache initialization see description. The cache is a separate storage environment used to store all the SKU types in the warehouse. With initial simulations running, the cache zone is filled with the quantity of 12 items of each sku type, based on the sub flow. Each sku type was assigned with a different color, so we have entirely 20 sku types with 20 colors.

Cache initialization

Fig 44. Cache initialization
Credit: Flexsim

While the cache is being filled, the rack storage will begin the process with one arrival with the quantity of 2500 items (as shown in the fig 42) in 20 sku types and all the quantity will be dispersed into 10 bays and get stored in their storage slots within 30 seconds of delay time and we assume those are the stored pallets where each pallet contains twelve items. Additionally, the SKUs remain the same throughout the entire simulation. Once the quantity reaches zero and the pallet is empty, the pallet content is set back to the number of items that are available in a full pallet.

fig 45. Cache Refill

## Credit: Flexsim

When the cache zone is empty, that is the process of refilling it. First, in each slot of the cache, a pallet is stored with the quantity of 12 items including the sku type. when order picking is being done, all the quantity data of the sku is batched in a cache slot, which clearly shows what type of sku is being picked and its quantity.

When the quantity in cache zone reaches zero, the ASRS vehicle drives in the aisle and picks up the pallets. Then it loads the quantity of 12 items of the SKU type on its platform according to the FIFO policy. After that, it waits for the slot to become empty. Once the slot is empty, it unloads the pallet into the destination slot. This process continues until all the orders are observed.

Fig 46. Random order creation and OP outside the warehouse
Credit: Flexsim
Fortunately, this process flow allows the picking of orders outside the warehouse to build mixed pallets. Since orders have been created randomly by random seed see fig 46 , it only allows one order at a time to be created. Once the cache initialization is complete, it will be filled with different sku's at the given quantity.

Orders will be generated randomly following uniform distribution, with the variety of items between 1 to 10 and the minimum of 1 sku to 10 sku types from 20 sku's. Each time an order is generated, the robotic arm will pick the pallet from the picking area and begin loading the items from stored pallets from the cache zone and unload them to the mixed pallet by following FIFO policy.

By the same token, the ASRS vehicle will load the items from the storage rack to the cache zone as well to unload them. Both work at once only when the slots are empty. Once the Mixed pallet is ready with ordered sku's outside the warehouse (cache zone), it will be moved to the final pallet storage to perform shipping. Every order data will be stored and batched automatically in an order history to measure the cycle time.

## Chapter 6

In this chapter complete analysis of experiments of two simulation models are explained with the results.

### 6.1 Analysis of Experiments

We used two simulation models developed to evaluate performance measurements. See fig 47. Analysis of experiment results is a step-by-step process used to retrieve raw data and show how results from the experiments are interpreted in flexsim.

Fig 47. Analysis of experiment results

## Credit: Author

In a nutshell, an experiment means a set of variables, replications and situations that are repeated using the same simulation model. We have performed two experiments for both inside and outside the warehouse simulation models using different scenarios.

In a simulation every time a simulation model is run, a scenario is defined. This means it's important to know how the variables will change. In our first experiment we are using five different variables with 32 different scenarios for two simulation models and 10 replications for each configuration. For the second experiment, variables were the same for two simulation models with 42 different scenarios and 15 replications of each configuration.

So, we have defined some fixed variables related to the system configuration for both the simulation models.

1. Number of Maximum Different SKU
2. Number of Maximum SKU
3. Order inter arrival time
4. Picking time
5. Number of Minimum Different SKU
6. Number of Minimum SKU

How the above-mentioned variables were used in scenarios and experiment tests will be discussed in the following sections.

### 6.2 Experiment Results

- Experiment 1

Picking inside and outside the warehouse with 32 scenarios

- Experiment 2

Picking inside and outside the warehouse with 42 scenarios
The two experiments we have done both were done for comparisons of the two simulation models from different scenarios, as opposed to the aforementioned outside Warehouse simulation model. See Fig 48. Picking inside the warehouse, below table
illustrates that 16 different scenarios where defined, with 6 different variables each, and three variables changing four levels each, they are; number of maximum different sku $(2,4,8,12)$ number of maximum sku $(2,4,8,12)$ and the order inter arrival time in seconds (200,400,800,1200).

Starting from one pallet being built per time, robot picking time is (o) which means inside the warehouse, and the minimum number of different sku and the minimum number of sku variables are ranked as (1). Different dimensions of an order were used to lead the simulation from order arrival to the order fulfillment.
\(\left.$$

SKU\end{array}\right]\)|  |
| :---: |
| 1 |

fig 48. Experiment 1 Picking inside the warehouse results.
Consider the scenario 1 to 16 , where the quantity of the item was chosen randomly from minimum and maximum values for a single order which ranges from 1 to 12. Table 1 - Scenario 1 and Column 4 - Using exponential distribution to calculate order inter-arrival time divide it by the number of consecutive orders. Then we find the average 200 seconds that each order takes.

As outlined earlier, scenario $(4,8,12,16)$ has the highest order completion time, 1200 seconds, when compared to the others because, as the quantity of sku has increased simultaneously, order arrival rate has increased. For these simulations, the minimum time required to complete the order is 200 seconds and the maximum is 1200 seconds for each scenario.

The figure 49 shows the picking outside the warehouse. It involves building a mixed pallet outside the warehouse, while using 16 simulation runs with 16 variables and 16 scenarios. All the dimensions of an order were the same when picking outside the warehouse but the robot picking time is intialised as (1). In the simulations, on average the minimum time required to complete an order is 200 seconds and the maximum time is 1200 seconds. As the number of skus has grown, the time needed to complete an order has grown as well.

| Scenarios | Number of Maximum Different SKU | Number of Maximum SKU | Order <br> Inter <br> Arrival <br> Time | Picking Time | Number of Minimum Different SKU | Number <br> of Minimum SKU |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 17 | 2 | 2 | 200 | 1 | 1 | 1 |
| 18 | 2 | 4 | 400 | 1 | 1 | 1 |
| 19 | 2 | 8 | 800 | 1 | 1 | 1 |
| 20 | 2 | 12 | 1200 | 1 | 1 | 1 |
| 21 | 4 | 2 | 200 | 1 | 1 | 1 |
| 22 | 4 | 4 | 400 | 1 | 1 | 1 |
| 23 | 4 | 8 | 800 | 1 | 1 | 1 |
| 24 | 4 | 12 | 1200 | 1 | 1 | 1 |

Fig 49. Experiment 1-Picking outside the warehouse results.

Picking inside and outside warehouse

Fig 50. Clustered column chart effects of 16 scenarios
The above figure 50 shows the effects of three variables of experiment 1 performance in clustered column charts., related to the first three vertical columns in figures 48 and 49. The green line, which represents the order inter arrival time, yellow line is the number of maximum sku and orange line is the number of maximum different sku indicates the performance of the system by the interaction of all three variables considered in the analysis. Thus, these variables are critical to evaluate the system's performance.

|  | Number <br> of <br> Maximum <br> Different <br> SKU | Number <br> of <br> Maximum <br> SKU | Order <br> Inter <br> Arrival <br> Time | Picking <br> Time | Different <br> SKU | Minimum <br> SKU |

| 20 | 8 | 12 | 1200 | 0 | 4 | 6 |
| 21 | 20 | 12 | 1200 | 0 | 10 | 6 |

Fig 51; Experiment 2-Picking inside the warehouse results.
In Experiment 2, there are 42 scenarios divided into 21 scenarios in which half the data is utilized for within the warehouse and half of the data is utilized for outside the warehouse which automatically shows the difference regarding the picking time. If the picking time is "o" then it is considered picked inside the warehouse and if it is " 1 " then it is considered picked outside the warehouse. It is clearly shown in both Fig 51 and 52.

Additionally, there are significant differences between the system's performance in terms of its results compared to experiment one: 21 different scenarios were defined with 6 different variables as in experiment one, and each of the 5 variables were changing at different levels, they are number of maximum different sku ( $2,4,8,20$ ) number of maximum sku $(4,8,12)$ order inter arrival time in seconds $(400,800,1200)$ number of minimum different sku (1,2,4,10) number of minimum sku (1,2,4,6).

In regard to scenarios, every scenario has different order dimensions with different variables to fulfill a single order. It has been discussed earlier that whenever the quantity of sku has been increased, simultaneously the order inter arrival time has increased. As a special case, take a scenario where the number of sku's are 20 and the maximum quantity is 12 , and in scenario 14 , the number of sku's are 8 and the maximum quantity is 12 .

For both the scenarios 14 and 15, there is still no difference in order inter arrival time since both scenarios are executed in 1200 seconds, since it is verified that it does not impact the order cycle time since the cycle time is computed from the moment the ASRS vehicle starts processing the order not from the time the order arrives.

The scenario 17 demonstrated that the number of different and minimum sku was not the same, they altered depending on the order dimensions but in relation to the effect of the number of sku's stored, they observe that the higher the quantity of sku as the longer the order cycle time. Even though variables were changing between order dimensions, the order cycle time remained unchanged. It was higher when the quantity of sku had increased and lower when the quantity of sku was decreased.

| Scenarios | Number of Maximum Different SKU | Number of Maximum SKU | Order <br> Inter <br> Arrival <br> Time | Picking Time | Number of Minimum Different SKU | Number of Minimum SKU |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 22 | 2 | 4 | 400 | 1 | 1 | 1 |
| 23 | 2 | 8 | 800 | 1 | 1 | 1 |
| 24 | 2 | 12 | 1200 | 1 | 1 | 1 |
| 25 | 4 | 4 | 400 | 1 | 1 | 1 |
| 26 | 4 | 4 | 400 | 1 | 1 | 1 |
| 27 | 4 | 8 | 800 | 1 | 1 | 1 |
| 28 | 8 | 12 | 1200 | 1 | 1 | 1 |
| 29 | 2 | 12 | 1200 | 1 | 1 | 2 |
| 30 | 2 | 4 | 400 | 1 | 1 | 4 |
| 31 | 2 | 8 | 800 | 1 | 1 | 6 |
| 32 | 4 | 12 | 1200 | 1 | 1 | 2 |
| 33 | 4 | 4 | 400 | 1 | 1 | 4 |
| 34 | 4 | 8 | 800 | 1 | 1 | 6 |
| 35 | 8 | 12 | 1200 | 1 | 1 | 6 |
| 36 | 20 | 12 | 1200 | 1 | 1 | 1 |
| 37 | 20 | 12 | 1200 | 1 | 1 | 6 |
| 38 | 4 | 4 | 400 | 1 | 2 | 2 |
| 39 | 4 | 8 | 800 | 1 | 2 | 4 |
| 40 | 4 | 12 | 1200 | 1 | 2 | 6 |
| 41 | 8 | 12 | 1200 | 1 | 4 | 6 |
| 42 | 20 | 12 | 1200 | 1 | 10 | 6 |

Fig 52; Experiment 2-Picking outside the warehouse
If you examine the scenarios 22 to 42, the order dimensions are similar. However, the picking was carried out outside the warehouse. Therefore, there is no difference between scenarios 1 to 22. However, if you look at scenario 29, variable 6 of the table of fig52, the number of minimum sku has changed from 1 to 2 and it has been increasing its value to 6 until scenario 42 .

As a consequence, both scenarios 21 and 42 have the highest order dimensions including a maximum of 20 different sku's and a minimum of 10 different skus. For a maximum quantity of 12 , the order interval time is 1200 seconds, a maximum value as per our order dimensions.

Significantly, the order cycle time was the same between scenarios 21 and 42 for picking inside and outside warehouses with same order dimensions. While there is no major difference between picking by robots and placing an order, it is anticipated that the number of the mixed pallets is set to increase, therefore the ASRS vehicle will have to travel to the rack locations to pick and store all the items ordered.

Fig 53. Clustered column chart effects of 21 scenarios
As we see the above fig 53, the effects of three variables of experiment 2 performance are illustrated in the clustered column charts., in relation to the first three vertical columns of fig 51 and 52 . Considering the green line which is the order inter arrival time, yellow line is no. of max sku and orange line is no. of max different sku shows their performance by all three variables considered in the analysis. See the Scenarios 15,16 and 21 has the max sku limit is ' 20 ' and the order arrival time curve has been changing from higher to lower and from lower to higher depending upon the quantity of sku's. The least order cycle time to complete a single order is 400 seconds and highest is 1200 seconds for different scenarios in both inside and outside the warehouse simulations.

### 6.3 Evaluation of Performance Measures

Finally, four different performances measures were collected they are:
1.ASRS Distance
2.Mean Service Time
3.Output

## 4.Mean Picking time

The above four are the key performance indicators (Kpi's) used to get the statistical outputs for two simulation models. For every kpi, the raw data has been gathered and transformed into a data table that was generated by statistics collector. Usually, A statistic collector would gather the raw data from the objects and events which were specified during a simulation run. Replication plots and frequency histogram graphs have been generated by using the data table for all the kpi's.

For comparison, we used only Mean service time data for two experiments to evaluate the performance of both inside and outside warehouse simulation models. Other kpi's data tables were collected and presented in the Appendix section below for the reference. After the data collection, it was carried an analysis of mean and variance to identify the factors that impacts the performance, Finally, the data were exported and recorded into an Excel file. Using this data, it was verified if the inside or outside warehouse picking method was equal or higher after comparison process finished.

| Mean (90\% Confidence) |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Sample Std Dev |  | Min | Max |  |  |  |  |
| Scenario 1 | 133.5 | $<$ | 141.2 | $<$ | 149.0 | 14.9 | 116.4 | 171.9 |
| Scenario 2 | 128.4 | $<$ | 137.5 | $<$ | 146.5 | 17.5 | 110.7 | 169.4 |
| Scenario 3 | 160.3 | $<$ | 169.2 | $<$ | 178.1 | 17.2 | 139.9 | 204.0 |
| Scenario 4 | 194.1 | $<$ | 212.8 | $<$ | 231.5 | 36.1 | 148.3 | 279.7 |
| Scenario 5 | 240.1 | $<$ | 263.5 | $<$ | 286.8 | 45.0 | 199.1 | 344.6 |
| Scenario 6 | 225.3 | $<$ | 240.6 | $<$ | 255.8 | 29.4 | 203.5 | 309.3 |
| Scenario 7 | 257.3 | $<$ | 287.1 | $<$ | 317.0 | 57.5 | 184.6 | 362.0 |
| Scenario 8 | 326.9 | $<$ | 359.2 | $<$ | 391.6 | 62.4 | 272.8 | 465.0 |
| Scenario 9 | 785.3 | $<$ | 979.0 | $<$ | 1172.8 | 373.7 | 464.6 | 1462.6 |
| Scenario 10 | 537.1 | $<$ | 604.8 | $<$ | 672.5 | 130.5 | 414.8 | 854.5 |
| Scenario 11 | 537.7 | $<$ | 661.2 | $<$ | 784.7 | 238.2 | 371.0 | 1314.5 |
| Scenario 12 | 544.0 | $<$ | 731.7 | $<$ | 919.3 | 361.9 | 365.1 | 1738.3 |
| Scenario 13 | 1666.8 | $<$ | 1959.3 | $<$ | 2251.9 | 564.2 | 1009.9 | 2707.4 |

Fig 54. Mean Service time data table of experiment 1
Considering the data of above fig 54; There were four factors used for statistics called Mean, sample standard Deviation, Minimum and maximum. The mean service time is the time where number of mixed pallets have been served under a fixed time period. Basically, in statistics, The confidence level indicates the probability. So, here the confidence interval is $90 \%$ that implies that we expect $90 \%$ of the interval which estimates there would be a statistically significant difference between the data. Sample standard deviation is the measurement of a distance between each data point and the mean. Simply we can say how much our sample data is distributed over the mean time.

At last, two statistical tests have done which is a way of mathematically proving that a certain statistic is reliable. It is to make a decision based upon the experiment result and the main intention is to determine whether we have got enough evidence to reject or accept a conclusion.

Replications Plot

Fig 55. Box chart of replications for scenarios and tests
Replications are nothing but getting the exact result when an experiment is repeated and also it is a single run of a simulation for a specific scenario. we have run the experiment with 32 scenarios and two statistical tests to verify whether the same result was obtained to detect smaller changes if needed. For each scenario, the data of maximum and minimum values ranging from o to 2500 were clearly shown in fig 54 ; by using box chart.

Frequency Histogram

Fig 56. Histogram chart for frequency of scenarios

From fig 54; The data of the second column was taken as 'Mean' until scenario 16 which was considered as the picking inside the warehouse and from 17 to 32 as picking outside the warehouse. Same applies for standard deviation see the fig 55 .

|  | Mean |  |  | Standard Deviation |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  | Std.Dev |  |
| Scenarios | Inside | Outside | Mean I/O | Inside | Outside | I/O |
| 1 | 141.2 | 54.8 | $258 \%$ | 14.9 | 6 | $248 \%$ |
| 2 | 137.5 | 74.6 | $184 \%$ | 17.5 | 13.5 | $130 \%$ |
| 3 | 169.2 | 139.7 | $121 \%$ | 17.2 | 46.3 | $37 \%$ |
| 4 | 212.8 | 191.3 | $111 \%$ | 36.1 | 47 | $77 \%$ |
| 5 | 263.5 | 133.1 | $198 \%$ | 45 | 60 | $75 \%$ |
| 6 | 240.6 | 166.3 | $145 \%$ | 29.4 | 60.3 | $49 \%$ |
| 7 | 287.1 | 258.8 | $111 \%$ | 57.5 | 57.5 | $100 \%$ |
| 8 | 359.2 | 354.2 | $101 \%$ | 62.4 | 56.9 | $110 \%$ |
| 9 | 979 | 505.7 | $194 \%$ | 373.7 | 256.1 | $146 \%$ |
| 10 | 604.8 | 452.1 | $134 \%$ | 130.5 | 162.9 | $80 \%$ |
| 11 | 661.2 | 510.9 | $129 \%$ | 238.2 | 124.6 | $191 \%$ |
| 12 | 731.7 | 752.2 | $97 \%$ | 361.9 | 301.2 | $120 \%$ |
| 13 | 1959.3 | 1065.2 | $184 \%$ | 564.2 | 323.4 | $174 \%$ |
| 14 | 1130 | 993.1 | $114 \%$ | 496.8 | 378.2 | $131 \%$ |
| 15 | 1148.6 | 1077.3 | $107 \%$ | 570.3 | 336.9 | $169 \%$ |
| 16 | 1209.1 | 1275.8 | $95 \%$ | 643.9 | 389.7 | $165 \%$ |

Fig 57. Mean and standard deviation results of experiment 1
As per the data table of Fig 57. Mean and standard deviation results of experiment 1, it clearly shows in the 4th column "Mean I/O" and 7th column "Std.Dev I/O" about the percentage level of both inside and outside warehouse picking. If we compare the percentage of both mean and standard deviation of each scenario, we consider below or equal to $100 \%$ is best to perform picking inside the warehouse and more than $100 \%$ is best for outside picking.

Looking at the scenario 16 , it has got $96 \%$ which is best among all and scenario 12,8 , are also showing better results. We can also consider the scenarios 4,7 , and 15 , But if we take a look on standard deviation scenario 3 has almost $37 \%$ which is faster to perform picking inside the warehouse. Also, the scenarios, 4,5,6,7 and 10 are showing
better results. If we compare the results of both mean and variance together scenario 7 has best output results.

Fig 58: Clustered column chart of Mean I/O of Exp-1

Fig 59: Clustered column chart of Standard Deviation I/O of Exp-1
At last, two statistical tests have done which is a way of mathematically proving that a certain statistic is reliable. It is to make a decision based upon the experiment result and the main intention is to determine whether we have got enough evidence to reject or accept a conclusion.

| Test 1 | 392 | 431 | 471 | 76 | 315 | 573 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Test 2 | 345 | 422.2 | 499 | 149 | 266 | 754 |

Fig 6o: Test Results of Service Time

| Test 1 | 204 | 205 | 206 | 2 | 201 | 208 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Test 2 | 214.5 | 222.6 | 230.8 | 16 | 202 | 261 |

Fig 61: Test Results of Picking Time
Regarding the results of service time and picking time in fig 60\&61, we got the same statistical output for two tests in service time i.e., 0.183013 then there is no significant difference. But we see the different output for picking time i.e., -3.670097 is for test 1 and 3.670097 is for test 2 .

| TEST 1 IN | TEST 2 OUT |

| 203 | 202 |
| 207 | 202 |

Fig 62: Test results of Inside and Outside picking

From the fig 63. To perform the tests for both inside and outside simulation models, order dimensions are same and the real time to pick the object is also same for two models. See the fig 64; blue line is the result of test in and orange line is the result of test out. According to the line chart outside picking is a bit faster compare to the inside picking.

## 63. Line chart results of Test In and Test Out

See the fig 64; Results of experiment 2 which is creating a pallet outside the warehouse. The data of mean and standard deviation has taken from the experimentation report of service time provided in appendix. As verified by the results, it is considered that if mean and standard deviation I/O result is below $100 \%$ then it is better to perform picking inside the warehouse or it is greater than $100 \%$ it will be best to perform picking outside the warehouse.

|  | Mean |  | Standard <br> Deviation |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Scenarios | Inside |  | Mean <br> I/O | Inside |  | Std.Dev <br> I/O |
| 1 | 143.7 | 85.3 | $168 \%$ | 10.9 | 11 | $99 \%$ |
| 2 | 183.1 | 141 | $130 \%$ | 19.1 | 25 | $76 \%$ |
| 3 | 225.5 | 195.9 | $115 \%$ | 26.8 | 36.3 | $74 \%$ |
| 4 | 253 | 167 | $151 \%$ | 34.7 | 25 | $139 \%$ |
| 5 | 301.2 | 264.5 | $114 \%$ | 43.1 | 53.9 | $80 \%$ |

Fig 64. Mean and standard deviation results of Experiment 2
Looking at the data table, scenario until 21 which was considered as the picking inside the warehouse and from 22 to 42 as picking outside the warehouse. Same applies for standard deviation. Scenario 10 has $80 \%$ of mean and $70 \%$ of variance among all the scenarios, it has best results. In this case it is best to perform picking both inside and outside because most of the scenarios has better results. But comparing to the mean standard deviation results are showing best output and almost 80 percent of the scenarios are showing below $100 \%$.

### 6.4 Comparison between the simulation models

Comparing the results of both simulation models when perform order picking, it was verified that both the models shown better results but picking outside the warehouse simulation presents a better performance than the picking inside the warehouse simulation in all scenarios analysed. Additionally, the picking outside the warehouse simulation model is less impacted by an increase in the number of SKU's stored. Which shows that this model works better than the other model in warehouses that deals with a higher number of SKU's.

Regarding the order inter arrival time as verified by the results, it also shows a higher performance than the first model when the order arrival rate increases. For smaller arrival rate the system does not present good performance in relation to the quantity of orders completed. This happens because both the models are able to build the mixed pallets during the interval between arrivals. The higher the arrival rate the more performance is shown.

About the robotic arm picking, it is a crucial variable for both the models to measure the performance. As the travelling process are connected to the picking and palletizing the items from the rack. When the results are verified it has shown that robotic arm picking items and making a mixed pallet outside the warehouse has better performance than the inside the warehouse, because storing the items in the cache
zone and picking the ordered items from the cache zone happens simultaneously. So, this model can execute both the process at the same time.

Besides, in the simulation model maximum and minimum number of sku's are stored based on the order requirements. As a conclusion both the simulation models were developed in this study, the results show that the second model tends to work better than the first one when the operation involves a high quantity of SKU's.

## 7.Conclusions

This study was designed to compare the features of euro fork's system with the new autonomous vehicle storage and retrieval system (AVS/RS) system and evaluate their performance to make comparisons between the two simulation models. As the demand for mixed pallets by warehouse customers increases, a new system was developed and designed. The "Eurofork" an Italian company wishes to combine the picking and palletizing processes in a better way to streamline the warehouse operations.

On both systems, order picking operations are mandatory and are performed by robotic arm. In the new system the order picking process occurs in front of storage racks and in the cache zone. In the new system, picking operations show impact on overall performance compared to eurofork's system as two simulation models are used to build mix pallets inside and outside the warehouse.

This is why the new system's performance was measured through simulation to perform its operation in a virtual warehouse, and the experiment results were used to make comparison and evaluation between the two simulation models to verify whether the new system will outperform the euro fork's system. Simulations were conducted under different scenarios to see how the variables impact on its performance and how the performance measures were calculated to get the output data to be compared.

In the end, experiments were conducted on two simulation models in order to compare which model gave better results. A quantitative analysis was done in determining which of the simulation models performs better, taking into consideration the data from all the scenarios and performance measures. Their results demonstrate that the new system has demonstrated superior results in order picking both inside and outside the warehouse.

However, the picking outside of the warehouse simulation model has better performance than the inside warehouse as it involves order picking operation with high quantity of sku. However, both the simulation models are equally good as they are not manually tested and examined, so we can implement both the models as per company needs.

However, the picking outside of the warehouse simulation model has better performance than the inside warehouse as it involves order picking operation with high quantity of sku. However, both the simulation models are equally good as they are not manually tested and examined, so we can implement both the models as per company needs.
